known as *Topfen* and cream as *Obers*, in France, *blé* may signify wheat as well as other cereals, and corn or maize might be translated as *mats* or *blé de Turquie*. If the present translations of 'hunk of bread' were used, there would certainly be disappointment in a recipient led to believe he would receive a *tartine* or a *Butterbrod*.

If it must be admitted that the perfect relief worker, like the poet, is born and not made, it may also be admitted that less perfect specimens might be brought appreciably nearer in quality to the ideal, after a careful study of the information and advice contained in this unpretentious but valuable little book.

THE HUB OF THE FUTURE WORLD

The Geography of World Air Transport

By J Parker Van Zandt. (America Faces the Air Age, Vol 1.) Pp viii+67 (Washington, D.C. Brookings Institution, London Faber and Faber, Ltd., 1944) 5s net

THE Brookings Institution was established in 1927 with the twin objects of "aiding constructively in the development of sound national policies and . . . to offer training of a super-graduate character to students of the social sciences". In pursuance of these objects, it initiated in 1943 a programme of economic research in aviation under the direction of Dr J Parker Van Zandt. The director has now prepared the introductory volume to a promised series, and he limits himself to outlining the basic setting of the world air transport problem.

The author points out the many erroneous ideas of the space relationships of the countries of the world which have arisen from the still all too common use of Mercator's projection for wall maps and atlas maps of the world. Curiously enough, much that he has to say may be novel to the American public, but is actually what has been taught in British schools for the past four decades. Americans may be shocked to find that Chicago is nearer to Istanbul than to Buenos Aires, and that Los Angeles is nearer Moscow than to Rio. "Most of the world that matters lies in one hemisphere . . . 94 per cent of all the people and 98 per cent of the world's industry", and the centre of that hemisphere is in western Europe. Actually London is used as the centre of what is called the "Principal Hemisphere". Of the eight major "trade areas", four dominate the world—Greater Europe, North America, U.S.S.R., and Asia—and the conclusion is reached that the future will confirm rather than reverse this position. It is thus regarded as a basic fact with respect purely to world air transport operations that the favoured position is at the hub of the hemisphere. While the disadvantages of America's peripheral position are partly offset by her gigantic industrial development and purchasing power, it is argued that more efficient operation and lower costs through greater volume will be needed to counter the handicap of longer average distance to world markets.

Attention is directed to the immensely strong position which could be held if only the countries of Greater Europe acted in unison. Despite the focal position of the British Isles, and the importance, above all others, of the difficult North Atlantic route, the suggestion is made that the limited land areas

available in Britain will be a handicap. Despite the war-time use of Goose Bay in Labrador, the author holds that the importance of trans-polar and high latitude routes has been much exaggerated.

That the main result of this frank American survey should be to affirm that "geography is still a controlling factor" and that Britain automatically becomes the centre of the future air-age world should give us in Britain food for serious thought. Forty years have passed since Sir Halford Mackinder wrote "Britain and the British Seas", yet technical progress and inventions have but underlined his concept of the importance of Britain's world position.

L. DUDLEY STAMP

BIOLOGY OF FLIGHT

The Biology of Flight

By Prof Frederick L Fitzpatrick and Karl A Stile. Pp vi+162 (London George Allen and Unwin Ltd., 1944) 8s 6d net.

THIS book attempts to cover a very wide field indeed, ranging from the flight of insects and birds, to aviation medicine, and the control of disease that may be spread by air travel. It gives very lucid if somewhat superficial description of these matters in a form which assumes no previous knowledge of the subject.

However, there is no need for simple treatment of a scientific subject to be inaccurate, unfortunately a number of inaccuracies suggest that the authors have little practical knowledge of, or very close contact with, some of the matters which they describe. For example, "from the practical standpoint . . . is considered unsafe for the average person to fly much above 20,000 ft because of the limits of present oxygen equipment". This is done almost every day by many thousands of pilots and air crews. Discussing Donati's altitude record of 47,358 ft (corrected), it is clear that the authors have overlooked the difference between corrected altitude and pressure altitude. Again, "a descent of 10,000 to 15,000 ft without ventilation of the middle ears will usually cause rupture of the ear drums". The factor causing rupture of the ear drums is the differential pressure to which they are subjected. This cannot be expressed in thousands of feet unless the absolute height is stated. Descent from 45,000 ft to 30,000 ft will not cause rupture.

The use of the word 'probably' in connexion with statements giving numerical data is out of place. The figures should be checked.

Some of the photographs are official British pictures from the Ministry of Information. The line illustrations are clear, but some do not seem to present an aspect of interest, for example, Fig 33. Fig 17, purporting to show the burning of a candle at various altitudes, bears little relation to the truth. It would have been better if the accurate photographic plate in Ruff and Strughold's "Atlas der Luftfahrtmedizin" could have been copied. Had the authors tried the simple experiment themselves with a candle, ventilated bell jar, and filter pump, they would have found a candle still burns dimly at the pressure corresponding to 40,000 ft.

There is a paucity of collected work on the biology of flight and a very definite place for an accurate simple treatise on the subject. It is a pity that the present book is marred by loose writing and misstatement.

B. H. C. MATTHEWS

CLIMATE AND HUMAN COMFORT*

By PROF. DAVID BRUNT, F.R.S.

Imperial College of Science and Technology, London

Bodily Reactions to Heat and Cold

THE temperature of the deep tissues of the human body is said to be 98.4°F in normal conditions, any large deviation from this value being uncomfortable, and in extreme cases fatal. It is generally stated that a rise of body temperature to 107°F is likely to be fatal, but there is no equally definite range of fall of temperature which can be regarded as fatal. Heat is continually being generated within the body, even during sleep, as the result of the chemical processes associated with breathing, digestion and physical effort, all these processes being grouped under the term metabolism. This heat is conducted to the skin, partly by the normal conducting power of the body tissues, partly by the blood-stream, and is dissipated from the skin to the environment. Heat cannot be conducted to the skin unless the temperature of the skin is lower than that of the deeper tissues of the body. Observations show that the skin temperature varies over different parts of the body, being lowest of all over the feet, and next lowest over the hands. From this we may appreciate that special care is needed in the design of boots and gloves for men exposed to conditions of extreme cold.

When the body is exposed to cold, the following reactions occur (a) the skin temperature falls, (b) there is an onset of shivering, an involuntary effort to increase the internal production of heat by muscular action, and (c) the adrenal and thyroid glands discharge fluids which accelerate the metabolic generation of heat.

When the body is exposed to heat, the sweat glands discharge sweat on to the surface of the skin, where it evaporates, and in so doing takes heat from the body. Heat is dissipated from the skin in three ways (a) by radiation exchange between the outer surface, partly clothing, partly uncovered skin which the body presents to the environment, (b) by convection of heat, which can be simply described as the carrying of heat from or to the surface of the body by the air coming into contact with it; and (c) by the evaporation of sweat.

There is in addition a small loss of heat in the respiratory passages and lungs, but in the discussion of the heat balance of the body we may neglect this item, though it may well be an important factor in determining comfort.

Indoors, the three items mentioned must balance the metabolic rate of generation of heat. Out of doors, in bright sunshine, the gain of heat from the unshine is effectively an addition to the metabolic rate. The convective loss or gain is proportional to the square root of the air speed, and the evaporation from unit wetted area of the skin, in given conditions of air temperature and humidity, must also depend on air speed in the same manner.

In low and moderate air temperatures, the evaporative loss of heat from the skin is practically independent of air temperature, and the only controllable modes of dissipation of body heat are those due to radiation and convection. These two factors are proportional to the difference between the temperatures of the surface of the body and of the air,

while the convective loss is also proportional to the square root of the air speed. Further, an increase in the amount of clothing worn has the same effect as putting an additional resistance into an electric circuit. It decreases the outward flow of heat and raises the skin temperature. The rate of loss of heat from the body can thus be decreased by wearing more clothing, by increasing the air temperature, or by decreasing the air movement, and it can be increased by reversing one or all of these possibilities.

In high temperatures, or during great physical exertion, the secretion of sweat and its evaporation is the main factor in the dissipation of heat from the skin. An examination of the measured rates of loss of heat by convection and evaporation shows the curious result that, even when the body appears to be completely wetted with sweat, the area of skin from which evaporation occurs is only about one third of the area from which heat is lost by convection. The rate of evaporation from unit wetted area is the greater the higher the wind speed, and the lower the humidity of the air. If, while the temperature is kept constant at such a high level that active sweating occurs, either the humidity is increased, or the air speed decreased, or both changes are made, the body responds by an increase of the wetted area of skin. The reverse of this statement is also true. No instrument can produce a parallel to this response, and so it is not to be expected that any instrument will enable us to measure in a simple manner the reaction of the human body to given atmospheric conditions.

We find that the human body can so react to a wide range of external conditions as to preserve the internal temperature at 98.4°F or near it. The skin tries to produce its own climate. This effort is most successful when one is just comfortably warm in bed, the temperature under the bedclothes being then $85^{\circ}\text{--}86^{\circ}\text{F}$.

Limits of Heat-stroke Conditions

A long series of measurements of the various factors involved in the heat balance of the body in controlled conditions of temperature, humidity and ventilation, made in the John B. Pierce Laboratory of Hygiene, Newhaven, Conn., by the Director (Dr C. E. A. Winslow) and Drs Herrington and Gagge, enable us to write down expressions for the magnitude of the heat losses from the body in any given conditions. The equation of heat balance of the body can be written in such a form as to give the highest relative humidity in which body temperature can remain constant, in given conditions of air temperature and ventilation. To allow for the possibility of very light ventilation, this is taken to be 17 ft per minute, and in what follows this rate of ventilation must be regarded as assumed, unless some other rate is specifically mentioned. It is also assumed that the temperature of the radiating solid surfaces in the environment is equal to the air temperature.

The details of the computation have been given elsewhere, and will not be repeated here. Fig 1 shows the results of five such computations. For men resting indoors, or in the shade, Curve AA gives the limit of tolerable conditions for a nude man, and Curve BB for a lightly clothed man. In conditions represented by a point to the left of the appropriate curve for nude or clothed men, the body temperature will not rise, while in conditions represented by any point to the right of the curve the body temperature will rise, and will continue to rise so long as exposure

* Discourse delivered at the Royal Institution on March 9

Fig 1* CURVES SHOWING THE LIMITS OF THE RANGE OF TOLERABLE CONDITIONS FOR VARYING DEGREES OF ACTIVITY, AA FOR NUDE SUBJECTS RESTING INDOORS, BB FOR CLOTHED SUBJECTS RESTING INDOORS, CC FOR CLOTHED SUBJECTS RESTING IN SUNSHINE, DD FOR CLOTHED SUBJECTS WALKING AT 4 M.P.H. (NO SUNSHINE), EE FOR CLOTHED SUBJECTS WALKING AT 4 M.P.H. IN BRIGHT SUNSHINE
* Figs 1, 2 and 3 are from Prof. Brunt's paper in *Endeavour* of July 1944

to these conditions is continued. With continued rise of body temperature, the blood-pressure falls, the pulse-rate increases, strong palpitation occurs, followed by a condition of stupor, ending in death by heat-stroke. It is seen in Fig 1 that the wearing of clothing affords considerable protection against heat, since, in completely dry air, the upper limit of tolerable temperature is about 138°F for a clothed man, and 113°F for a nude man.

Nothing that has been written above should be regarded as excluding the possibility of remaining for short periods in air at temperatures far beyond the limits prescribed by Curves AA and BB of Fig 1. In the *Philosophical Transactions of the Royal Society* of 1775 will be found several papers by Dr. Charles Blagden, later secretary of the Royal Society, in which are described experiments in rooms kept at very high temperatures. Blagden stayed in a room, in which the air temperature was maintained at $240^{\circ}\text{--}260^{\circ}\text{F}$, for a period of eight minutes, during the first seven minutes he experienced no discomfort, but the subsequent rapid increase of distress in breathing and of a feeling of anxiety caused him to leave the room after a total stay of eight minutes.

In Fig 1 Curve CC represents limiting conditions for a lightly clothed man, sitting in bright sunshine, Curve EE the limits for a clothed man walking at 4 m.p.h. in bright sunshine, and Curve DD the limits for a clothed man walking at 4 m.p.h. on a cloudy day.

A ready check on the limits set by Curve BB in saturated air is fortunately available. It has been pointed out by the late Dr. J. S. Haldane that in saturated air in coal mines a temperature of 88°F is about the highest temperature which can be tolerated, even by men not doing any work. This close agreement affords some confirmation of the reliability of the computations on which Fig 1 is based. Exposure to conditions in which body temperature rises by $1\text{--}1\frac{1}{2}^{\circ}\text{F}$ per hour produces no permanent injury, provided the exposure is not continuous over a long period. Thus with periodic withdrawal to cooler conditions, miners can work in conditions in which long-continued exposure would end in heat-stroke.

Acclimatization

It is generally acknowledged that within limits, it is possible for a man to accustom himself to living and working in temperatures above or below the normally accepted limits. Acclimatization to hot conditions consists largely in training the sweat glands to function efficiently, and perhaps in part in learning to avoid strenuous exertion. In temperate climates some degree of acclimatization is necessary at the beginning of each summer, since the sweat glands are inactive during the winter. When a very hot day comes at the beginning of summer, it is far more distressing than an equally hot day later in the summer.

Men who work in the very hot deep mines of South Africa are subjected to a regular process of acclimatization, first doing very light work in hot stopes, and then increasing slowly their rate of work. But even after acclimatization, when working in the hotter mine, coloured workers show a definite rise of internal temperature, sometimes amounting to 2°F or more when working in air, say, of temperature 85°F and relative humidity 98 per cent (wet bulb temperature 84.6°F), and ventilation 20 ft per minute. In saturated air there can be no loss of heat from the skin, either by convection or by evaporation, and sweat unless the skin temperature is higher than the air temperature. Further, if heat is to be transported to the skin from the deeper tissues, the internal temperature must be higher than the skin temperature. So, when a man works in saturated air at 95°F , his skin temperature must be higher than 95°F , and his internal temperature must be several degrees above the normal value, probably $101^{\circ}\text{--}102^{\circ}\text{F}$ at lowest.

Effect of Increased Ventilation

It is easy to compute limits of tolerable conditions with any selected rate of air motion, for nude subjects. The extension of the preceding work for clothed subjects is not at the moment possible. The conductivity of the clothing with air speed 17 ft/min has been evaluated from experimental data, but there is not available any series of observations from which the conductivity of clothing can be related to the air speed.

Fig. 2 THE EFFECT OF VENTILATION ON HEAT-STROKE CONDITIONS FOR NUDE SUBJECTS. THE CURVES GIVE LIMITING TOLERABLE CONDITIONS, *aa* FOR AIR MOVEMENT 0.085 METRE PER SECOND (17 FT PER MINUTE), *bb* FOR 0.25 METRE PER SECOND (50 FT PER MINUTE), *cc* FOR 0.5 METRE PER SECOND (100 FT PER MINUTE), *dd* FOR 1 METRE PER SECOND (200 FT PER MINUTE), *ee* FOR 2 METRES PER SECOND (400 FT PER MINUTE), *ff* FOR 5 METRES PER SECOND (1,000 FT PER MINUTE). FIGURES SUCH AS 200g MARKED ON THE CURVES INDICATE THE RATE OF LOSS OF WATER PER HOUR BY EVAPORATION FROM THE WHOLE BODY, SKIN AREA BEING ASSUMED TO BE 1.8 SQUARE METRES.

Fig. 2 reproduces a series of curves for six values of the air speed. It is seen that in a wind of a little more than 2 m.p.h. the limits are given by *dd*, and with relative humidity 60 per cent, the tolerable temperature is about 6° F higher than with air speed .7 ft/min., while in completely dry air the corresponding rise in tolerable temperature is nearly 20° F. The numbers shown on the curves indicate the rate of loss of water from the skin by evaporation of sweat, from the whole body of a man of average size (Skin area 1.8 sq metres, or 19.4 sq ft). For example, the 130 g indicated on Curve *aa* at 95° F, relative humidity 72 per cent, indicates that a man resting indoors in such conditions would lose water from the body by sweat at least at the rate of one pint in a little more than four hours. The 1,150 g shown at temperature 110° F, relative humidity 42 per cent, indicates that a man resting in the shade in these conditions with a wind of 1,000 ft/min. (11.1 m.p.h.) would lose water by sweating at the

rate of at least two pints per hour, while the figure of 2,370 g lower on the Curve *ff* indicates a loss of more than half a gallon per hour.

There are two aspects of these high rates of sweating which deserve further consideration. In the first place, sweat is not pure water, but contains, in addition to various organic compounds, common salt, and the salt lost by sweating must be replaced, or serious consequences to health will follow. Of these consequences miner's cramp is frequently cited as a typical example. In the second place, it should be noted that it is possible for dehydration of the body to cause sweating to stop. The consequences may be fatal. If, for example, a man is exposed to a wind of just over 11 m.p.h., at a temperature of 110° F and relative humidity 42 per cent, his body temperature can remain normal so long as he sweats at the rate of about two pints per hour. If he stops sweating, he will thus be exposed to conditions in which radiation and convection heat the body, while

there is no evaporative loss of heat from the skin. His body temperature will then rise, and he will die of heat-stroke. This appears to be the explanation of the deaths from the Smoom, the hot dry Poison Wind of Arabia, in which whole parties of men have perished together.

In very hot air of any assigned temperature and humidity, for any assigned rate of sweating there is a limiting air speed at which sweat is evaporated as rapidly as it is secreted. An increase of air speed beyond this limit, when a man is already sweating at his highest possible rate, will not increase the evaporating cooling, but will increase the convective heating, of the body. The body temperature will then rise, and will go on rising so long as the high air speed is maintained. This effect is to be observed in hot mines, where there may be a limit to the air speed in which efficient work is possible.

Classification of Climates

In Fig 3 are collected together such information as can be applied to classify climates. We have to allow for the possibility of very light winds. Lines *BB*, *CC* and *EE* are copied from Fig 1. To the right of *BB* conditions are intolerable for long-continued exposure. Between *BB* and *CC* a man cannot rest in bright sunshine without rise of body temperature or risk of heat-stroke, and cannot make any physical effort without such risk. This area in the diagram is marked 'very hot'. In conditions represented by the area between *CC* and *EE* a man cannot walk at 4 m.p.h. in bright sunshine without rise of body temperature, and the corresponding area in the diagram is marked 'warm'. At the other end of the temperature scale, it is generally agreed that at temperatures below 50° F it is cold, and at temperatures between 50° and 60° F it is cool. We are therefore left with an area bounded by the 60° F vertical line and the curve *EE*, which will contain the zone of possible pleasant conditions.

Within this range of conditions, by wearing suitable clothing, it is possible to do light work indoors or in the shade without sweating, and to rest without shivering. Experience in air-conditioning has confirmed this, and has shown that, with medium relative humidity, men can do light work indoors with the maximum degree of comfort in temperatures between 60° and 76° F. The optimum temperatures prescribed by heating and ventilating engineers are, in the United States, 76° F in summer, 72° in winter, in England, 66° in summer, 62°-64° in winter.

Very high relative humidity is oppressive at high and moderate temperatures, and raw at low temperatures. Very dry air is keen at low temperatures, while at moderate and high temperatures it is at first stimulating, but ends by producing irritation, headaches, and a marked tendency to becoming quarrelsome. The Fohn wind, a warm dry wind which blows down the sides of many mountain ranges, has long been notorious for producing these effects of irritability and quarrelsomeness, and dwellers in some desert regions manifest an undesirable permanence of irritability.

Fig 3 is based on an assumption which was stated earlier, but requires emphasizing, that the temperature of solid surfaces is the same as the air temperature. There are conditions in which this assumption is not justified, particularly in hot sunny climates, in which the walls and roofs of houses and any solid objects exposed to the sunshine attain a

very high temperature. When this occurs, the radiation from the solid surfaces in the environment will be much greater than would be computed on the basis that they are at air temperature. Contact with very hot solid objects leads to a degree of discomfort which can only be described as little short of misery. Most white men find that a temperature of 105° F is near the limit of tolerability in these conditions.

It follows that there are two types of hot climates (a) the oppressive, warm, damp type of climate, usually with overcast skies and little fall of temperature at night, and (b) the hot dry sunny climate, the undesirable nature of which has been stressed in the last paragraph. Comfort is determined by the temperature, humidity and rate of motion of the air. If air-conditioning were possible, we should treat (a) by drying, and (b) by cooling, the air indoors. In the absence of air-conditioning, all that can be done in case (a) is to increase the ventilation, or to sit in the greatest draught. In case (b) increase of ventilation is not effective, and it is better to close all doors and windows of the house in the early morning while the air is still cool, and to ventilate indoors by electric fan where possible. The oppressive warm, damp climate calls for an open type of house permitting free air movement, while the hot, dry, sunny climate calls for a house having double walls and roof, with a wide air space, and capable of being closed up fairly tightly against the intrusion of the hot outer air during the day.

In India, a simple expedient is frequently adopted for cooling the air in houses, water-soaked curtains or tatties being hung over doorways through which air enters the rooms. The evaporation of water from the tatties into the air cools the air, by taking from it the latent heat required for evaporation. Now in such a process of evaporation, while the dry-bulb temperature falls, the wet-bulb temperature of the air remains constant. But it would be found that along any of the curves of Figs 1 and 3, the wet-bulb temperature falls as the temperature rises. In other words, a given wet-bulb temperature becomes more uncomfortable, for any degree of physical effort, in any degree of ventilation, as the dry-bulb temperature increases.

The Ideal Climate

Can we now determine the ideal climate? To this question a definite answer can be given provided we have a clear statement of the *idea* underlying the search for the *ideal*, and we must avoid the common error of regarding the climate in which it is pleasant to spend a summer holiday as the ideal climate in which to live permanently, and to do one's work. Before we can determine the ideal climate we must, in fact, know for what degree of activity the climate must be ideal. Clearly the ideal will not be found either in the very cold polar regions or the very hot tropical regions. In a paper published some two years ago, I endeavoured to solve the first stage of the problem by postulating that it should be possible for a lightly clothed man to walk at four miles per hour in the sunshine without sweating, and to sit in the sunshine, or stand or sit in the shade or indoors doing light work, without shivering. With relative humidity of about 60 per cent, the temperature to fit this prescription will be between 66° and 68° F, and the optimum is thus 67° F. For the nude man the optimum temperature will be about 4° higher, say 70°-71° F.

Fig 3 A TENTATIVE CLASSIFICATION OF CLIMATES

Major S F Markham, in his book "Climate and the Energy of Nations", has directed attention to the fact that, on a world map of annual mean temperatures, the 70° isotherm passes through, or close to, all the centres of early civilizations in Egypt, Palestine, Assyria, Sumeria and Persia, and not far north of Mohenjodaro, the centre of the early civilization in the valley of the Indus. Thus the early civilizations arose in regions where the mean temperature of the year is now, and probably was then, 70° F or very near it, and as they were founded by men who wore so little clothing that we may regard them as nude, we may take this as a confirmation of the estimate given above of the ideal temperature for the nude man.

An annual mean temperature of 70° F would mean summer temperature well above the limit, and a winter temperature well below it, so that the summer months would be too hot, and the winter months too cool, for comfort. With the development of methods of indoor heating in winter, the optimum conditions would shift to climates where the summer was less extreme, but the winter cold not such as to make indoor heating impossible, as exemplified in ancient Greece, and still more notably in the Roman Empire. With the fall of the Roman Empire, indoor heating became far less common, and almost died out, and the next major civilization, the Muslim, arose again in the region of the 70° F isotherm. Later, in western Europe, as indoor heating developed, and houses once again became weather-proof, civilization began to make rapid strides.

We can now go a stage further, and state that for healthy and active life the climate must be such

that the mean temperature of the hottest month shall not exceed 70° F, or at most 75° F, while the coldest month of the year shall not be so cold that it becomes difficult or expensive to maintain a comfortable temperature indoors. Markham (*loc cit*) states that when a white man migrates to a country where the mean temperature of the hottest month of the year exceeds 75° F he finds that, whereas he and his children may be able to tolerate the changed conditions, his grandchildren will show a marked loss of energy and of mental and physical efficiency. Markham suggests that the 'poor white' problem which has arisen in many hot countries is a result of migration to unsuitable climatic conditions. It is unlikely that any simple hard-and-fast rule can afford a solution of the problem of desirable climates. Some allowance must be made for the effects of low relative humidity and of high wind speed, in modifying the disabilities of hot climates.

An examination of world maps of mean temperatures for each month of the year shows that only a very small fraction of the land areas satisfies the condition that the hottest month of the year has a mean temperature not above 75° F, while the coldest month of the year has a mean temperature not below freezing point. The largest single area satisfying these conditions is that part of western Europe which includes the British Isles, France, northern Spain, Switzerland, Germany, the Netherlands, Denmark, and a strip along the south-western shores of Scandinavia. Within this area, there is a higher level of health and prosperity than in the neighbouring regions.

Markham quotes a considerable volume of statistics

relating to health and prosperity for different countries, showing the lowest death-rate and the lowest infantile mortality for the years 1926-35 to be those of New Zealand, the country which I have always regarded as having the best climate of all countries in the world. Over most of New Zealand the mean temperature of the hottest month lies between 62° and 70° F, and that of the coldest month between 45° and 52° F. We might compare these figures with the corresponding figures for the British Isles, where the July mean temperature lies between 58° and 62° F, while the mean temperatures of the coldest month of the year lie between 39° and 44° F. In the British Isles, temperature readings above 90° F are infrequent, and values exceeding 95° F are decidedly rare, being generally confined to the inland regions of the southern half of England. In the British Isles the highest temperature recorded during a month may exceed the mean for that month by about 20° F in winter, and by about 30° F in summer, while the lowest temperature recorded may fall below the mean of the month by about 30° F in winter, and by about 20° F in summer.

Development of the Weather-proof House in England

The weather-proof house required glass for the windows, bricks for parts at least of the structure, and the fireplace and chimney as we know it. The history of the development of these three features in England is by no means clear. Houses were glazed in the Roman Empire, but the making of glass disappeared from Britain with the Romans. The Venerable Bede described how, in 675, Benedict, when building a church at the mouth of the Wear, had to go to France to find and bring back glass workers to glaze the windows of his church. Bede further states that these glaziers not only glazed the church windows, but also taught the English how to make glass. The knowledge they imparted was not lasting, for in 758 we find the Abbot of Jarrow appealing to the Bishop of Mainz to send him a craftsman in glass. The earliest evidence we find of glass-making in England refers to 1230, in which year a deed granted certain lands at Chiddingfold in Surrey to one Lawrence, "vitrarius". Chiddingfold was apparently the earliest centre of glass-making, but English glass was poor in quality until the sixteenth century. Even then glass windows were so rare and valuable that they were often bequeathed, like jewels, apart from the house. The decision by the Court of Common Pleas in 1599, that glass windows should not be removed from a house, reveals the prevailing state of things with regard to windows.

Aubrey, an antiquarian writer of the seventeenth century, said that glass windows were rare except in churches and gentlemen's houses until the time of Henry VIII, and added that to his own remembrance, copyholders and poor people in Herefordshire, Monmouthshire and Shropshire had none before the Civil War. Aubrey also wrote that before the Reformation, ordinary men's houses "had no chimneys, but flues like *louvre* holes. Some of 'em were in being when I was a boy".

So far as definite records are available, bricks were first made in England (at Hull) in 1303, and only became reasonably good and cheap a century later. One of the earliest examples of brickbuilding in England, with English bricks, is the north and east part of Queens' College, Cambridge, built in 1448.

There are still to be seen in England a few houses

with fireplaces and chimneys as we know them dating back to the middle of the twelfth century, as for example the Norman House at Christchurch, Hants (the ruins of which are in the gardens of the King's Head Hotel), built between 1125 and 1150, and a house at Boothby Pagnell, Lincoln, built about 1150. But chimneys as we know them only became common about the time of Henry VIII.

We can thus say that by the time of Henry VIII the weather-proof house had become possible in England, but was still too expensive except for the wealthy, and that it was late in the sixteenth century before it became widespread throughout the country. The development on the Continent was roughly parallel with that in England. Once weather-proof houses had become general, England had a great advantage in its cheap supply of coal for indoor heating, and it may not be a fortuitous coincidence that the glories of Elizabethan England came soon after the advent of the weather-proof house.

MICROBIOLOGY

ITS BASIC CONCEPT AND ITS FUTURE

By DR A C THAYSEN

Director, Colonial Microbiological Research Institute,
Trinidad

IT will probably be conceded that the terms 'microbiology' and 'biochemistry' can be roughly translated into English as the knowledge of invisible life and as the chemistry of the living cell respectively. As such, these definitions aptly circumscribe the fields of study embraced by the two branches of science. Yet, all too often, the term microbiology is referred to as synonymous with that of biochemistry, as if these two branches of science dealt with identically the same problems, required the same training, and would use the same approach to the solution of their problems. This, however, is not necessarily the case and has no foundation in the basic concept of microbiology.

If one searches for this basic concept, one must eventually be led back to the living cell itself as it exists in its natural habitats. For only by a study of the changes which the cell performs under such conditions does it appear possible to obtain a correct insight into its functions, and only by an evaluation of these functions under controlled growth conditions can a measure be obtained of the future possibilities of the science of microbiology. This is undoubtedly the lesson to be learned from the polemic between Pasteur and Liebig in their writings on the function of yeast in fermentations, and it is the axiom insisted upon by Koch, when he demanded that, before a disease can be ascribed to the action of an organism it is essential to grow the suspected type under artificial conditions free from all others and to produce with the cultured specimen the identical symptoms in healthy animals which had been observed to occur in diseased forms under natural conditions.

A primary function of microbiology then appears to be the study of micro-organisms in their natural habitats and to endeavour to isolate them from these for cultivation under artificial conditions with the view of reproducing natural changes or any other changes of which they may be found capable.

The knowledge which has accumulated^o since Leeuwenhoek first observed micro-organisms in droplets of water has shown, not only that the invisible population of the earth is as abundant as is its macroscopic counterpart, but also that it is met with in places and under conditions which would be utterly inadequate to sustain the life of higher organized plants or animals. This presupposes a flexibility in the make-up of the free-living microscopic cell which far exceeds that of any higher organized living being and gives an insight into the diversity of the problems with which microbiology may be called upon to deal. On the other hand, a study of the natural habitats of micro-organisms should make it possible to circumscribe the limitations of this branch of science.

For example, the microscope reveals that, where water is present, even in the form of a humid atmosphere, free-living microscopic cells can be met with almost anywhere. On the surface of inert objects, in the arctic ice, in the sea, in the soil, in the hot springs of volcanic localities, in subterranean oil wells, on the surface of living plants and animals, in the intestinal tracts of animals and throughout the interior and exterior of dead and dying animal and vegetable tissues, actively growing microscopic cells are present. In such varying habitats, then, must they find conditions which make it possible for them to survive and to propagate their kind.

On the other hand, where water is absent it may safely be predicted that no microscopic life can persist, and it may positively be asserted, for example, that the so-called 'curse' of the tomb of Tutankhamen could not possibly be ascribed to microbiological life, as was done in some quarters when this tomb was opened and found devoid of moisture.

There are, of course, other limitations, such as temperature and reaction, but the range here is often extraordinarily wide, much wider than would be feasible among higher cell organizations.

A particularly interesting form of limitation of types rather than of numbers is met with in the soil and among the microflora and microfauna of the intestinal tract of most animals, where a few types have established themselves irrespectively of the feeding habits of the animal. Though a much wider range of types must originally enter the intestine they appear unable to survive in competition with the established forms.

The mechanism by which such specialization is brought about can only be ascertained by a study of the habits of the living cell itself. It is conceivable that the rate of growth of the established types may be faster than that of the accidentally entering cells, either because the conditions prevailing favour the former, or that the normal types during their growth produce substances which are harmful to all but the established types. Whatever the explanation, the example given illustrates the influence which the natural habitat may exercise on the organisms living in it and indicates the importance which must be attached to its study.

An extensive exploration of some of these habitats began during the second half of the nineteenth century. Because of the utilitarian aspect of this study it resulted not only in added knowledge and in a widening of the field of microbiology, but unfortunately also in a subdivision of the science into at least four different and more or less water-tight compartments: medical, or pathological bacteriology, dairy bacteriology, soil bacteriology, and the mycology of the fermentation industries. Though

this specialization may have been unavoidable at the time, it did much to obscure the potentialities of microbiology. It is undoubtedly responsible for the neglect of many fields of exploration, such as the microflora of oil wells and oil storage tanks, of the rotting of textiles and of the corrosion of metallic structures in soils and water. How important an extension of the exploration of natural habitats of micro-organisms can be, can be seen from the modern developments in sewage purification and in the retting of textile fibres.

Turning to the free-living cell itself and to the bearing which its study must exercise on the progress of microbiology, it appears appropriate to illustrate this by a few examples. The first which comes to one's mind is the revolution which was caused in the brewing industry by the introduction of pure cultures in the brewing of lager beer. There are many others which carry equal weight, such as the prophylactic treatment of infectious diseases with pure cultures of certain pathogenic organisms, the preparation of 'starters' for cream used in butter-making, the inoculation of deficient soils with cultures of specific strains of nitrogen-fixing bacteria and, to take a more recent example, the use of micro-organisms in the assay of vitamins.

If it be conceded, then, that a knowledge of both the living cell and of its habitat is essential for the successful expansion of microbiology, it is relevant to ask how such knowledge should be circumscribed. Obviously it should be as comprehensive as possible and should embrace all relevant information on the morphology, the biology, including cytology and physiology, and the chemistry of the cells, the latter, both as regards their composition and their functions. An exclusive study of one or two of these aspects would fail to give a balanced picture of an organism and would in many cases lead to an erroneous estimate of its potentialities. For example, in the case of the preparation of gluconic acid by certain fungi, the conversion of the sugar used is governed by the biochemical properties of the organism. But it is influenced also by its morphology, for it has been shown that the action of the fungus used on the sugar which it converts to gluconic acid can be greatly increased by a change in the morphology from matted hyphae to smaller cell aggregates which can be more uniformly aerated than the mats of hyphae.

Again, in the production of baker's yeast, an industry which is based on the ability of certain yeasts to build up their cell substance from carbohydrates and inorganic nitrogen, the rate of growth of the cells is markedly influenced by the number of cells present in their habitat at any given time. Here a study of the growth-rate of the individual cell will indicate the conditions required to secure full advantage of the biochemical process of the organism.

Finally, a case may be cited in which the exploration of the biochemical activities of an organism supplied the clue to the connexion between its growth and the spoilage of fish living in the proximity of its natural habitat. It had been observed that trout and salmon entering certain rivers became useless as a food because their flesh became contaminated with a pungent earthy taint. The origin of this taint remained obscure until an examination of the river beds revealed extensive areas covered with the growth of a micro-organism which produced a volatile organic nitrogenous substance. This substance, when dissolved in high dilution in water in

which fish were living, imparted to their flesh the same earthy taint with which the spoiled fish had been tainted

Reverting to the significance of biology in microbiological research, it is relevant to point out that without its aid it would be impossible to describe an organism and to compare or identify it with known types for eventual classification and conservation. Neglect in this respect has been responsible in the past for much confusion, and many types already studied have been lost in the course of time with little hope of recovery, because their original description was wholly inadequate for them to be re-identified. Within the last two decades a serious effort has been made to remedy this state of affairs by the acceptance of a standard code of identification and by opening in various countries specialized collections of type cultures in which recognized types of micro-organisms are maintained and into which new types can be incorporated as they become known, each provided with a comprehensive description, covering its general biological characters, its relationship to other types, as well as any special pathogenic, chemical or other properties which it may possess.

Turning to the place of chemistry in microbiology, it is probably correct to claim that its functions should be twofold. It should explore the relevant changes in a habitat which result from the metabolism of micro-organisms, and it should investigate the chemical composition of the organism itself so that information may be obtained on its food requirements. Further, the intermediary products which result from its activity should be explored so that the steps can be ascertained by which the final metabolic products are arrived at.

In the course of time chemistry, as applied to micro-organisms, has branched off into a third direction which cannot be regarded as strictly relevant to its main function. This side-line originated in the observation that the metabolic processes of micro-organisms are fundamentally similar to those of higher organized forms of life. The free-living microscopic cell, therefore, with its much contracted life-cycle, is often chosen for the study of metabolic changes, which might not be as conveniently explored on tissues removed from higher animals or plants.

Within its more legitimate sphere, the chemistry of micro-organisms covers a wide field of unexplored ground, in spite of the not inconsiderable amount of information which has been acquired already. Such knowledge makes it possible, for example, to predict with some measure of assurance the nature of some of the chemical compounds which can be produced by micro-organisms and the stages through which the substances utilized by the free-living microscopic cell are broken down into final metabolic products. This is particularly so in the case of the carbohydrate metabolism of micro-organisms. Much less is known about the changes through which nitrogen passes under their influence, and still less of those in which sulphur, phosphorus, silicon and other elements may be involved.

As for the carbohydrates, it may be said that, whether they be polysaccharides or monoses, hexoses or pentoses their breakdown by micro-organisms gives rise to the same ultimate products—carbon dioxide and water. Some organisms fail to utilize carbohydrates to this extent and more complex end-products will result, notably organic acids, alcohols,

ketones and esters. But even in such cases, and in spite of the seemingly endless possibilities, the number and the nature of the end-products will be restricted to comparatively few groups. This is due to the standardized type of enzyme reaction employed by micro-organisms in metabolizing carbohydrates, even where the organisms belong to the most varied biological groupings.

It is for this reason that the application of micro-organisms in the preparation of organic compounds from carbohydrates must remain a limited field of application, a field which in the course of time, and for economic reasons, may become even further restricted than it is to-day. Where fermentation processes have already been introduced, for example, in alcohol manufacture and in the production of citric, lactic and acetic acids, they have in most cases maintained their economic predominance. That they will do so in future is already problematic, at any rate in the case of lactic and acetic acids, other than vinegar. For these acids can now be produced more cheaply by chemical methods than by fermentation. That vinegar is still made commercially with the aid of micro-organisms illustrates the advantage possessed by fermentative processes in such industries as brewing and wine production, which are based on the conversion of carbohydrates into products in which subtle and often undefinable metabolic substances constitute an essential part of the final product.

It has already been mentioned that the biochemical aspect of the nitrogen metabolism of micro-organisms is far less explored than that of carbon. Nevertheless, micro-organisms have been, and are being, used on the largest scale in processes which are based on the nitrogen metabolisms of such organisms. The fixation of atmospheric nitrogen in the soil by addition of pure cultures of certain bacteria is a case in point, removal of undesirable tissues from hides in leather manufacture, sewage disposal, casein digestion in cheese-making, and protein synthesis from inorganic nitrogen compounds are others.

A very special interest is attached to the chemical exploration of bacteriostatic and bacteriolytic substances produced by micro-organisms, substances into the composition of which nitrogen enters. A purely biological approach to this subject, though an essential preliminary, would not suffice for full advantage to be gained from the existence of these substances. Their production by micro-organisms at any given time may often be totally inadequate for large requirements, and they will, moreover, often be difficult to isolate from the substrates in which they have been produced biologically. The final goal here would appear to be their chemical identification and synthesis by the organic chemist.

Recent work on the sulphur metabolism of micro-organisms has brought to light several interesting observations which indicate that this field also may be of interest not only to the biologist but also to the chemist, the farmer and the engineer. For it has by now been established that certain micro-organisms, through their sulphur metabolism, play a significant part in the corrosion of metallic structures which are exposed in soils or water. Others influence soil fertility through their sulphur metabolism.

The fields of the phosphorus and silicon metabolism of micro-organisms remain almost unexplored. If experience gained in other fields may be taken as a guide, an exploration here could most profitably be approached by a study of those micro-organisms

which occur in places where phosphorus or silicon undergo 'spontaneous' changes

This brings the discussion back from a contemplation of the functions of chemistry in microbiology to the question of the significance of the free-living cell in its natural habitat, a question which has already been referred to as fundamental. It seems appropriate at this juncture to substantiate its contention by a further example

Where micro-organisms develop in their natural habitats they do so at the expense of substances which can serve their energy requirements. Such substances may range from highly complex organic compounds to simple elements. The result of the action of micro-organisms on them will inevitably be a change in their chemical composition, a change which, if undesirable from a human point of view, will be characterized as destructive

The destructive activities of micro-organisms are so manifold to enumerate, ranging as they do from the taking of human life to the elimination of dead vegetation, from the spoilage of milk and all other foods to the mildewing of fabrics, from the consumption of gas stored in gasometers to the destruction of natural rubber, or the breakdown of liquid fuels, or the corrosion of metallic structures. The study of all such destructive activities and a clarification of their significance must always constitute a major function of microbiological research, worthy of a degree of attention at least equal to that devoted to the adoption of micro-organisms as catalysts in the production of organic substances.

What bearing, it may finally be asked, has all this on the planning of future microbiological research?

It implies that the biological aspect should be safeguarded in greater measure than has been done in the past, and that a more general approach to the subject should be encouraged, not, be it understood, at the expense of specialized investigations, but in addition to and in amplification of them.

There will be needed in future a more comprehensive survey of the natural habitats of the microscopic world than has hitherto been undertaken. There is needed to-day for a much more thorough exploration of the destructive activities of micro-organisms than has so far been conducted. There is need for a better understanding of the symbiotic and antagonistic activities of micro-organisms, and of the adaptive properties of the microscopic world in its natural habitats. There is need for more work connected with the classification and preservation of type cultures, and for a fresh approach to an understanding of the biological and biochemical principles underlying established microbiological processes.

Improvements in such processes could not fail to result from such work. Finally, there is need for the training of workers in general microbiological principles. Planning of microbiological research on the above lines is unlikely to be effectively undertaken in laboratories designed for specialized purposes such as pathology, dairying, soil investigations or biochemistry.

A homestead for general microbiological research is needed suitable for carrying out also the training of workers on more general lines than has been customary in the past. By whom such an establishment should be conducted, by universities or under Government auspices, may be a matter for discussion. Of its usefulness there can be but one opinion.

OILFIELDS IN GREAT BRITAIN*

By DR G. M. LEES

Anglo-Iranian Oil Co., Ltd

IN *Nature* of March 31, 1934, an article on "Petroleum in Great Britain" gave the following conclusion on the prospects

"Oil pools of commercial magnitude (*pace* natural gas, shale oil and allied indications and potentialities) cannot reasonably be anticipated in any known area in Great Britain. Many years of official geological survey—a centenary in 1935 in point of fact—together with much independent work, leave few spots unknown, if not in detail, at least in sufficient outline to preclude even faint hope"

On December 6, 1944, G. M. Lees and A. H. Taitt read a paper to the Geological Society of London on "The Geological Results of the Search for Oilfields in Great Britain" and the president of the Society, Prof. W. G. Fearnside, on opening the discussion, said that "Never before had so much exact and new information about the underground geology of Britain been presented to the Society. The D'Arcy Exploration Company's [the exploration subsidiary of the Anglo-Iranian Oil Co.] delivery of some 300,000 tons of native oil had been a notable contribution to the war effort, but the by-product of knowledge gained of Carboniferous rocks, under and about the edges of the coalfields, was not less vital in the interests of the nation"

The pessimistic, though confident, opinion of 1934 was presumably written without a full appreciation of the capacity of the modern technique of geophysics and of rapid exploration drilling to probe the structural and stratigraphical secrets below the unconformable cover of Permian and Mesozoic strata. This blanket completely obscures the older rocks throughout extensive areas in the Eastern Midlands, East Anglia and south-central England, and such borings as had penetrated below the unconformity were too few and too scattered to allow any satisfying deductions to be drawn from their results. These areas were, therefore, virtually *terra incognita* at depths below a few thousand feet, or less, from surface.

The exploration programme of the D'Arcy Exploration Company has extended over a number of separate and unrelated geological prospects—the Mesozoic in southern England, the Carboniferous in the western and eastern Midlands, the Permian in North Yorkshire and the 'Calcareous Sandstone Series' in Scotland. During the course of the past ten years, intensive geological and geophysical work and the drilling of fifty-two deep and forty-three shallow exploration borings by the Company have yielded an immense amount of new information. They have proved five oilfields and two areas of natural gas, and these fields are now producing from 243 wells. The total production up to the end of 1944 was 337,000 tons. The crude oil is of good quality, with good light and lubricating oil fractions. The specific gravity ranges from 0.83 to 0.89.

The oilfields are situated about eight miles north-west of Newark at Eakring, Duke's Wood, Caunton and Kelham Hills, and there is one isolated small field at Formby, between Liverpool and Southport. The Nottinghamshire oilfields produce from depths of 1,900–2,500 ft from sandstones in the Millstone Grit Series and, to a lesser extent, from sandstones

* Published by permission of the chairman, Sir William Fraser, and the directors of the Anglo-Iranian Oil Co., Ltd.

in the basal part of the Coal Measures. The oil is concentrated in the crestal parts of minor anticlines forming part of a major anticlinal area which extends from the Trent at Rolleston to the vicinity of Ollerton. The Formby oilfield is a small accumulation in Keuper Waterstones sealed upwards by Glacial clay, and in this case the oil is produced from a depth of 100–120 ft. The structure is a faulted monocline, but it is thought probable that the oil has migrated upwards from a lower source, perhaps in the Carboniferous. Two deep borings have been made to explore the lower possibilities, but so far without result.

The gas-fields are at Aislaby in Eskdale, North Yorkshire, and at Cousland near Dalkeith, Scotland. In the former case the reservoir rock is a Permian limestone, and in the latter it is the sandstones of the Oil Shale Group of the Calciferous Sandstone Series. Short tests have indicated that the gas may be present in sufficient quantity to justify commercial exploitation.

The discovery of the Nottinghamshire oilfields resulted from geophysical work carried out, for the most part, by the staff of the Anglo-Iranian Oil Company. Seismic refraction arc surveys have proved to be the most successful method, whereas the reflexion method has given disappointing results. Gravity and magnetometer methods have also been used. These geophysical surveys have revealed the presence of a number of structural highs in extensive areas in eastern Nottinghamshire and in Lincolnshire, and a number of these have already been tested by drilling, although the ratio of success to failure has been low, the search continues.

An immense amount of new geological information on the stratigraphy and structure of the Carboniferous rocks below the Permian unconformity has been revealed by these borings. Coal seams of significant thickness have been penetrated by borings at Spital, Dunston and Stixwold, north, south and south-east respectively of Lincoln City. The coal seams lie at about 4,000 ft depth, and although for this reason they are not likely to be mined in the near future, they represent a substantial addition to the known British reserves of coal. It is possible that coal seams at shallower depth may be present underground in the surroundings of the Wash or even in north Norfolk, the former possibility was already envisaged by Prof. Kendall many years ago. On the debit side of the coal account, the area north of Newark, both east and west of the River Trent, has been proved to lack coal seams of important thickness, while to the south of Newark there is a considerable area in which there is an exceptional development of volcanic rocks within the Coal Measures, at the expense of workable seams. Farther south, however, there is an improvement, as a boring at Widmerpool, eight miles south east of Nottingham, has proved two good seams.

Another important by-product of the search for oil has been the discovery of potash salts of Permian age in Eskdale, North Yorkshire. Both sylvite and polyhalite are present, and this result shows that the potash deposits of the Zechstein Sea, which have such economic importance in north-west Germany, extend also into north-eastern England. The potash beds in Eskdale are at a depth of 3,650–4,775 ft and, while this may exceed easy mining depth, there is a possibility that the deposits may extend farther north towards the Tees valley and rise to a lesser depth.

Inevitably, after several decades of rural spoliation by uncontrolled industry, a certain apprehension has

been felt lest the development of oilfields might be at the expense of the amenities of the countryside in Britain but it need not and has not been so. Every care has been taken to cause as little disturbance as possible, after a well has been drilled, the derrick removed and only a small pumping jack marks the position of the boring. Electric power is used for pumping, and the motors are both small and silent. Buried pipelines carry the oil from the fields to railway siding whence it is transported in tank cars to a refinery.

OBITUARIES

Engineer Vice-Admiral Sir George Goodwin, K.C.

ENGINEER VICE-ADMIRAL SIR GEORGE GOODWIN GOODWIN, who died at Havant on April 2, was the sixth to hold the important position of engineer-in-chief of the Fleet—an office created in 1847. The first two holders, Thomas Lloyd and Sir Jam Wright, were civilians, but after the latter retired in 1887, the holders have all been naval engine officers. Richard Sennett, an inspector of machinery following Wright and he in turn being succeeded by Engineer Vice-Admirals Sir John Durston, Sir Henry Oram, F.R.S., and Sir George Goodwin. These four distinguished officers were all products of the admirable system of training inaugurated by the Admiralty in the dockyards and at the Royal Naval College, Greenwich.

Goodwin, who was born in 1862, became an engineer student at Portsmouth and received part of his education in the Dockyard School. Whilst a boy, he attained the highest position in the Cambridge Local Examinations and thereby became available for a scholarship at the University of Cambridge. He chose to continue his naval career, however, passed through Greenwich with distinction and except for about four years afloat, was afterwards employed either at Chatham Dockyard or at the Admiralty. He rose through the old ranks of assistant engineer, engineer and chief engineer, to the new ranks of engineer commander, engineer captain and engineer rear-admiral before, in 1917, on his succeeding Oram, reaching the highest rank at present open to a naval engineer officer.

In Goodwin's early days, there were many ships with low-pressure boilers and simple-expansion engines. He saw these types of machinery give way to compound- and triple-expansion engines, steam turbines, water-tube boilers and other important innovations. Known to a large number of officers afloat and ashore, he helped to bridge the gulf which existed between the engineering staff at the Admiralty and engineer officers in the Fleet, and on his retirement was entertained at dinner in the Grand Hotel, London—a unique occasion.

Among Goodwin's honours was that of the honorary degree of LL.D. conferred upon him when he attended the James Watt centenary celebration at Birmingham in 1919, as the Admiralty representative. He was the first naval engineer to be recognized by any university in Britain.

After his retirement from the naval service, Sir George Goodwin threw himself heart and soul into the work of various technical institutions, and in 1925 joined the old-established shipbuilding and engineering firm of J. Samuel White and Co., Ltd. of East Cowes, of which he became chairman.

Dr. G. L. Taylor

THE untimely death of George Lees Taylor at the age of forty-eight has robbed medicine and genetics of an able and industrious worker who had made notable contributions in this field. Born in 1897 at Ashton-under-Lyne, the son of Albert Taylor, he graduated in medicine at the University of Manchester

in 1920 after a distinguished undergraduate career. After two years of resident hospital appointments, Taylor spent seven years in general practice, but in 1929, when the chance occurred to become John Lucas Walker Student with Prof H. R. Dean at Cambridge, Taylor decided to abandon practice and devote himself to teaching and research. During the next six years Taylor's work was chiefly serological, and he published a series of ten papers on reciprocal reactions which established his reputation for painstaking and consistently sound work. During this time he was awarded the M.D. with commendation (Manchester) and the Ph.D. (Cambridge).

When, in 1935, the Rockefeller Foundation enabled the Galton Laboratory, University College, London,

to establish a special department for the study of blood groups in relation to human genetics, Taylor was ripe to take charge of this work, and he threw himself into it with characteristic zeal and determination.

Detailed study of the blood groups and their genetics had received but little attention in Great Britain, and Taylor had first to establish reliable methods and criteria for the A, B, O groups, the M and N factors and such other blood group factors had been described elsewhere. To widen his experience he studied for a time in Denmark with I. J. V. Jørgensen, and during 1935-39 he busied himself with the distribution of blood groups in Great Britain and with investigations upon rare human anomalies such as Huntington's chorea and acholuric jaundice.

At the outbreak of war Taylor at once took charge of the Galton Serum Unit established in the Department of Pathology, Cambridge, to provide adequate

supplies of reliable grouping serum for war purposes, and it is scarcely too much to say that the swift development of reliable Blood Transfusion Services throughout Great Britain would scarcely have been possible without the help so freely and willingly given to all by Taylor and his staff. As a result of his carefully standardized testing sera, reliable blood grouping results were placed within the reach of all services and hospitals, the volume of serum thus dispensed involved Taylor in a constant struggle to maintain adequate supplies of standard reagents—a work ungrudgingly pursued, the difficulties of which are often inadequately recognized. In spite of so much daily routine, Taylor continued his scientific work and was able to publish a further series of papers on the distribution of blood groups and subgroups in Great Britain based on a very much larger number of tests performed in the Transfusion Services. Taylor was quick to appreciate the scientific importance of the Rh factor, and his appeal with Mollison for samples of blood from the mothers of babies with erythroblastosis met with an excellent response which enabled him to pursue this subject so vigorously that within less than two years he and his collaborators had described seven allelomorphs of the Rh factor and four different types of anti-Rh serum. These results were obtained quite independently of simultaneous studies in America by Wiener, Levine and others, but the work of Taylor and his associates provided a welcome clarification of the confused state of American terminology, and Taylor's name will always be associated with the classification of the allelomorphs of the rhesus factor.

G. L. Taylor was a quiet, unassuming man, always ready to give his time to smoothing away the difficulties of others in what was an abstruse and difficult field. His friendly, helpful personality endeared him to a wide circle of friends, by whom he will be greatly missed. Our sympathy goes out to Mrs. Taylor and her young daughter.

D. F. CAPPELL.

NEWS and VIEWS

Colonial Microbiological Research Institute

THE Colonial Office announces that it has been decided to establish in Trinidad a Colonial Microbiological Research Institute, for the general study of microbiological problems in tropical conditions. The Institute will be under the general supervision of the Colonial Products Research Council, and will be financed from funds provided under the Colonial Development and Welfare Act, 1940. The first Director of the Institute will be Dr. A. C. Thaysen, of the Chemical Research Laboratory, Department of Scientific and Industrial Research.

He has been responsible there for the fundamental work on which a food yeast factory, now in course of erection in Maricao, has been planned. Dr. Thaysen is leaving Trinidad to discuss the siting and construction of the Institute's laboratories and connected matters. It is hoped that, when the Institute is under way, it will be possible to afford facilities for postgraduate work by visiting men of science in addition to the work of the staff of the Institute itself (see also p. 564 of this issue).

Scientific Activities in Paris

DURING the past few months, a few men of science in France have been able to visit Great Britain and to take up again the threads of scientific intercourse. Now we are able to welcome the re-appearance of *La Nature*, the well-known popular journal of science and its applications, after three years of suppression. The first issue, dated January 1, 1945, consists of only sixteen pages, and it is shorn of its attractive cover, but it contains well-illustrated articles on penicillin and its manufacture and on the solar corona, and a useful map of French broadcasting stations with data of their wave-lengths, powers, etc. The Editor announces that the journal will be devoted, as before the War, to the popularization of science, its applications, its methods and its significance for human progress. Later issues are equally attractive, the articles being well illustrated and maintaining a nice balance between pure science and its applications. *La Nature* is being published twice a month at 10 francs a copy. Another sign of increasing scientific activity in Paris is a comprehensive programme of

public meetings arranged by the French Association of Scientific Workers under the auspices of the Centre National de la Recherche Scientifique, which have been going on since early spring. The meetings have been divided into lectures on laboratory technique, public lectures on current scientific topics and visits to laboratories. The programme, which contains more than a hundred entries, reveals an enthusiasm that augurs well for the resurgence of science in Paris.

Physical Society · Presentation of Duddell Medal

At a meeting of the Physical Society to be held at the Royal Institution at 4 p.m. on May 23 the Duddell Medal for 1944 will be presented to Dr F. W. Aston in recognition of his invention and subsequent development of his mass spectrograph. This instrument, first designed and constructed in 1919, made use of a new and ingenious method of electromagnetic focusing and enabled Aston to establish that many elements consist of mixtures of isotopes, as foreshadowed by J. J. Thomson's work on neon. With later modifications of the instrument, Aston investigated most of the known elements and showed that all the stable isotopes, of which he discovered hundreds, had nearly integral masses, taking O as 16. Aston's later work is concerned mainly with the small deviations from this whole-number rule, representing the binding energies of the isotopes in the nucleus. Using a much improved mass spectrograph, he measured masses with a precision of 1 in 20,000 and determined the binding energies in isotopes of the lighter elements with great accuracy. Finally, from the masses and the photometrically determined relative abundances of the isotopes, Aston calculated "chemical atomic weights" for comparison with, and as a check upon, the results of other methods. At the same meeting, Prof. E. N. da C. Andrade will deliver his presidential address, taking as his subject "The History and Future of the Physical Society".

Belgian Delegation in Britain

A SECOND group of Belgian professors, representing the Belgian Fondation Universitaire, is visiting Britain for a fortnight at the invitation of the British Council. For five of them it is their first visit to this country. The delegates are Prof. Jean Brachet, Faculty of Science, Brussels; Prof. Marcel Homes, Faculty of Science, Brussels; Prof. Henri Koch, Faculty of Comparative Physiological Science, Louvain; M. Marius Lecompte, keeper of the Belgian Royal Museum of Natural History; Prof. Jean Louis, State Agricultural Institute, Gembloux; Prof. Victor Van Straelen, Faculty of Science, Ghent, and Brussels; Dr. Pierre Wigny (law and legal science); Prof. Jean Haesaert, Faculty of Law, Philosophy and Letters, Ghent; Prof. Paul Rousseau, Faculty of Law, Louvain; Prof. Paul de Visser, Faculty of Law, Louvain. Among the places the delegation will visit are the British Museum, the Imperial College, Kew Gardens and the Bureau of Micrology, University College, London, the London School of Hygiene and Tropical Medicine, the Society for Visiting Scientists, Rothamsted Experimental Station, Oxford and Cambridge.

Advisory Committee on Building Research

The Minister of Works has appointed a scientific advisory committee to advise on and to suggest lines of scientific research, to suggest where this research could best be carried out and to keep it under review,

and to advise on the practical possibilities and further development of the results of current research. The committee consists of Prof. J. D. Bernal (physics, Birkbeck College, London (chairman)), Dr. E. F. Armstrong, member of Building Research Board, Prof. J. F. Baker (mechanical sciences), University of Cambridge, Prof. P. M. S. Blackett (physics), University of Manchester, Prof. W. E. Curtis (physics), University of Durham, Dr. C. C. Douglas, University of Oxford, chairman, Joint Committee on Heating and Ventilation (Building Research Board and Industrial Health Research Board), Prof. C. D. Ell (physics), King's College, London, Prof. I. M. Hebron (organic chemistry), Imperial College of Science and Technology, London, scientific adviser, Ministry of Production, Prof. J. M. Mackintosh (public health), University of London, Mrs. J. V. Robinson, lecturer in economics, University of Cambridge, Sir Ernest Simon, chairman, Advisory Council, Ministry of Fuel and Power, Mr. F. E. Smith, chief superintendent, Armament Design Dept., Prof. W. N. Thomas (engineering), University College, Cardiff, and Prof. S. Zuckerman (anatomy), Universities of Oxford and Birmingham. Mr. I. Sir Reginald Stradling is executive officer.

Release of Requisitioned Land and Premises

THE second report from the Select Committee on National Expenditure for the Session 1944-5 deals with the release of requisitioned land and buildings. It emphasizes the weaknesses in existing land legislation which were stressed during the debate in the House of Commons on the Requisitioned Land and War Works Bill, and shows the need for incorporating in the Bill provisions to amplify the assurances which Sir John Anderson gave to the House of Commons in that debate. An instance cited is the report of an airfield constructed on 600 acres of farm land and 260 acres of common land in the 'green belt', into which the Select Committee inquire shows that existing legislation fails to protect common land or to provide for its reinstatement. The menace to the countryside which still persists is shown by two further examples: the Admiralty's claim to Bodmin Moor, rich in archaeological interest and potentiality for research, and also an important catchment area for use as a bombing range—since dropped—and the War Office inability to say whether the tract between the Frome River and Studland and Swanage Bay, cleared for training purposes, is to be restored to public use.

On the question of premises, the Select Committee's report indicates that the fundamental principle is the same, and its principal recommendation is that a supervisory authority should be entrusted with the task of pressing for the release of requisitioned premises, bearing in mind urgent civilian needs, and a central and independent review of the use of premises and of storage requirements should be instituted and pressed forward with all practical speed. But while a valuable system of co-ordinating the release of requisitioned land and premises has been devised, the little use that has so far been made of it is not to be attributed entirely to departmental reserve or inaction. It is due at least partly to the absence of decisions at the centre. The report recommends that the Government should not only come to an early decision whether it is more

to the national disadvantage to sterilize space by housing surplus stores or to scrap the stores, but also provide the departments, with the least possible delay, with the directions as to the strength and organization of the defence forces required after the War, which will enable them to determine which properties they will need to acquire and which of those now held they will eventually be able to release. Besides, the Select Committee recommends an independent review by the Government of the practice of departments in the retention of stores, and in this connexion the advice of Government scientific and research organizations should be sought in classifying stores according to their probable future use, having regard to scientific progress. The procedure for declaring stores obsolete also requires speeding up, and surplus stores and scrap arising overseas should, wherever possible, be disposed of without being brought back to Great Britain. Subject to political and strategic considerations, the fullest use should be made of storage facilities overseas for stores required for the war against Japan.

Museums as Contemporary Educational Centres

A MEMORANDUM received from Mrs. M. Harrison, acting curator of the Geffrye Museum, London, E.2, deals with the present-day problems of the creative use of leisure in an industrialized society—the education of children of a non-academic turn of mind, and the bridging of the gap that still tends to lie between school and the actualities of life. It is suggested that the solution lies in the establishment of centres specially equipped to show the individual, on a scale within his grasp, his place, meaning and purpose within the contemporary world. These centres could present in an appropriate manner a variety of visual material culled from industrial, commercial and public sources. They could also provide for courses of instruction in art and craft work and in contemporary social studies, educational film shows, facilities for study, and a scheme for loans to schools, with the view of encouraging further the individual's practical interest in, and investigation of, his or her surroundings in relation to the world at large.

Most of the plan is very feasible—indeed, several of the methods advocated have for some time been in successful operation in the 'village colleges' of Cambridgeshire; but it is difficult to accept the suggestion that it would be possible "to show the contemporary world . . . the direction in which the whole world is moving", either for reasons of exhibition space, or of opinion. There is much within it, however, which might well claim the attention of 'centres' already in existence, such as the larger provincial museums. For example, some of these in presenting the geology of their various areas are already 'illustrating' the fundamentals (not mentioned in the plan) inseparable from some industries. Upon such foundations the institutions concerned might profitably build along the lines suggested, and thereby help to refute the accusation (recently made at a meeting of the British Association) that the majority of museums in Great Britain are 'out of touch with modern life'.

Burrell Art Collection for Glasgow

THE Corporation of the City of Glasgow reports this important acquisition in its Art Gallery and Museums Report for the year 1943-44. Sir William Burrell's collection, which consists of pictures, tapestries, stained glass, furniture, carpets, porcelain,

ivories, enamels and silver, has long been associated with his name. It is probably most widely known for its tapestries, which include many of international importance. While presenting this valuable material for the cultural benefit of Glasgow, the donor has at the same time made provision for the purchase of additional works of art (more especially for those of the Gothic period), and for a special building to house it. This building will eventually be erected in the country not less than sixteen miles from the city.

Cancer Control in Peru

THE August issue of the *Boletín de la Oficina Sanitaria Panamericana* contains an interesting article on this subject by Dr. Julio Bedoya Paredes, of the National Institute of Radiology of Peru, who states that since this Institute was founded two years ago a record has been kept of cases according to the site of the cancer, classification, treatment and results. The Institute includes a reception service, specialized clinics, such as gynaecology, surgery and internal medicine, X-ray, basal metabolism, laboratory and histopathology sections, statistical, health education and preventive sections. It is intended to create a biopsy service through which specimens may be sent by air to the Institute for diagnosis.

Announcements

DR. J. F. J. DIPPING, head of the Chemistry Department at the Mining and Technical College, Wigan, has been appointed head of the Science Department at the South-East Essex Technical College, Dagenham.

To encourage the reading of papers by student members of the Institute of Fuel, also those taking courses at universities and technical colleges, the Council has decided to make an annual award of a medal together with a prize consisting of books and instruments to the value of £5. Particulars can be obtained from the Secretary, Institute of Fuel, 30 Bramham Gardens, London, S.W.5.

At the anniversary meeting of the Royal Institution held on May 1, the following officers were elected: *President*, Lord Rayleigh; *Treasurer*, Sir Robert Robertson; *Secretary*, Dr. A. O. Rankine; *Managers*, Prof. E. N. da C. Andrade, Dr. F. H. Carr, Sir Charles Darwin, Prof. Herbert Dingle, Dr. P. Dunsheath, Viscount Falmouth, Prof. G. I. Finch, Prof. C. L. Fortescue, Captain H. L. Hitchins, Mr. James Kewley, Mr. Arthur Marshall, Prof. H. R. Robinson, Dr. G. Shearer, Mr. H. S. Souttar, Sir George Thomson; *Visitors*, Brigadier R. A. Bagnold, Mr. J. G. Bennett, Mr. M. G. Bennett, Major W. H. Cadman, Dr. W. H. J. Childs, Mr. F. P. Dunn, Mr. Kenneth Gray, Dr. Wilfred Hall, Mr. James Henshilwood, Dr. W. Jevons, Mr. L. B. W. Jolley, Mr. G. S. W. Marlow, Prof. L. C. Martin, Mr. E. Kelly Maxwell, Prof. H. J. Plenderleith.

A COURSE of six lectures on "The Problem of Freedom in a Planned Society" to be delivered on Wednesdays, beginning May 16, at 7.30 p.m., at Victory House Hall (N.S.P.C.C.), Leicester Square, London, W.C.2, has been arranged by the Progressive League. The speakers include Prof. H. Levy, Major Adrian Stephen, Prof. M. Polanyi, Prof. F. A. Hayek, Dr. C. A. Smith, and Prof. D. Mitrany. Tickets, 6s. for the course, 1s. 6d. for single lectures, can be obtained from the secretary of the Progressive League, 20 Buckingham Street, London, W.C.2, or at the door.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

Extra X-Ray Reflexions from Diamonds

Dr. R. S. Krishnan and Mr. G. N. Ramachandran have stated¹ that they are not able to confirm my observations on type II diamonds, and they conclude that "The objections which Mrs. Lonsdale has raised against the interpretation of the X-ray reflexions observed with diamond given by the Bangalore workers are thus believed to be without experimental foundation".

Fig. 1.

Two years ago, however, Sir C. V. Raman, after stating his theory, continued: "The appearance of the quantum X-reflections with one kind of diamond and their non-appearance in the other kind then follows as an immediate consequence. In other words, this difference in X-ray behaviour of the two kinds of diamond is actually a proof . . ."² I am afraid that the Bangalore workers cannot have it both ways. If the difference in the two types of diamond is an immediate consequence of Raman's theory, then Krishnan and Ramachandran's denial that any such difference really exists does not support the theory, but contradicts it.

I am not concerned, however, with proving or refuting a theory; at this stage, facts are more important. As I understand their letter, Krishnan and Ramachandran have found a group of three extra spots for type I diamonds, whereas for type II diamonds they have found only one extra spot. This spot is rather diffuse; but coincides in position with the strongest of the three type I spots. They conclude that it is, in fact, the same spot. These data show that the diamond orientation used in their experiments was as shown in Fig. 1(a), the $[1\bar{1}0]$ axis being vertical (normal to the plane of the diagram) and the angle of incidence near the Bragg angle. I fully agree that in this orientation, the positions of the sharp spot found only for type I and of

the diffuse spot found for all diamonds are nearly identical (see p. 317, paragraph (6) and Plates 35f, 38d, and 39d of my paper³). In type I diamonds the diffuse spot forms a background to the sharp spot; in type II diamonds it exists alone; but without the evidence of the accompanying streaks or streaky spots, it is certainly difficult to distinguish the two effects.

If the diamond is turned through 180° about the normal to the (111) reflecting plane, however, so that its orientation is as shown in Fig. 1(b), no such possibility of confusion arises. The X-ray effects found in this orientation are as shown in the photographs and explanatory diagrams (Figs. 2a and 2b).

In this orientation the diffuse spot found for type II diamonds is clearly *not* equivalent to any of the three extra type I diamond spots A, B or C. It differs from them in intensity, shape, diffuseness, behaviour with change of temperature and of crystal mis-setting from the exact Bragg angle. It becomes larger and much more diffuse as the mis-setting increases, whereas the three type I spots A, B, C become slightly smaller and remain sharp. It is also temperature-sensitive, and they are much less so. This diffuse spot found for type II diamonds corresponds in all respects with the diffuse spot found at the centre of the A, B, C group for type I diamonds in orientation (b), except that it is more intense, because type II diamonds are inherently better reflectors. I have taken more than six hundred Laue photographs of various diamonds and have confirmed these observations again and again. The similarity between the diffuse (thermal) spots in the two types of diamond and the entire absence in type II of the sharp extra spots characteristic of type I photographs has been proved not only for the $\{111\}$ reflexions but also for $\{220\}$ $\{113\}$ reflexions in various orientations.

Krishnan and Ramachandran say that their type II diamond diffuse spot was very little temperature-sensitive. I offer the following explanation. Type II diamonds are not only mosaic, but also they often show definite distortion, such as slight spiralling of

Type I diamond: orientation as in Fig. 1b.

Type II diamond: orientation as in Fig. 1b.

Fig. 2.

the crystallites⁴. The result of this distortion is that although the real diffuse spot does vary with temperature, it is sometimes partially overlaid by a sharper and more intense distortion spot which does not vary with temperature. Using a large crystal and big X-ray beam, as Krishnan and Ramachandran appear to have done, it is easy (in orientation Fig. 1a) to confuse this sharp distortion spot with the sharp spot found for the near-perfect type I diamonds. They occur in the same place. In orientation (b) this confusion is quite impossible, especially if a really fine X-ray beam is used, so as to obtain maximum resolution. I suggest that Dr Krishnan and Mr Ramachandran should turn their diamonds through 180° about the normal to the reflecting (111) plane and test orientation (b) using a $\frac{1}{2}$ -mm diameter cylindrical collimator, and that they should look for the {220} and {113} effects in the two types of diamond and compare these also. I think that this controversy about a question of experimental fact would then cease.

Frictional Properties of Wool Fibres

THE friction apparatus devised by Bowden and Leben¹ to examine the friction of metals has been used to study the frictional properties of wool fibres. Some accessories were made to adapt the apparatus to the application of loads of 0.05–1 gm and the measurement of small frictional forces, but in essentials it remains the same as described by the above authors. The modifications enabled a single fibre mounted in a bow to be carried forward with a speed of 0.01 cm sec⁻¹ while pressed against a cylindrical piece of ram's horn with the required load. The horn was mounted on a strip of clock spring, the deflexion of which, recorded photographically by a moving-film camera, was a measure of the frictional force.

'Stick-slip' phenomena similar to those previously obtained¹ were recorded. The with-scale and anti-scale directions along the fibre were readily distinguished by the magnitude of the frictional force and the character of the stick-slips (see graphs a and b). The effect of wetting the fibre could be studied easily. Particular attention was paid to the variation in the two coefficients of friction (μ_1 and μ_2) with the pH of the wetting fluid, and to the effect of treating the fibre with shrinkage-reduction processes.

Typical values for the coefficients (horn-wool) obtained under several conditions are given in the accompanying table.

Speakman and Stott² have used the quantity $\frac{\mu_2 - \mu_1}{\mu_1}$ to give a measure of the tendency of individual fibres to undergo unidirectional migration which is recognized as the cause of wool felting and garment shrinkage. In view of the considerable difference between μ_2 and μ_1 , a directional coefficient defined by $\frac{\mu_2 - \mu_1}{\mu_2 + \mu_1}$ is preferred here. The directional

* Treatments commonly used to reduce the shrinkage of woollen goods

coefficient is increased by wetting the fibre, and the increase is greater in acid and alkaline than in neutral media (see Table, No. 1). The rate of felting is also greater both in acid and alkaline solutions than in neutral. Speakman, Stott and Chang³ have attributed this to the increased extensibility of the fibres in such solutions, but it is probable from these results that the increased directional friction also contributes.

As can be seen from the table, Nos. 2–5, shrinkage-reduction processes reduce the directional friction in alkaline solutions. This would cause a reduced rate of felting and would account for their effect in

STICK-SLIP TRACES OF WOOL FIBRE ON HORN

(a) Dry wool against scales (b) Dry wool with scales (c) Wool wet with water, pH 10.8, against scales (d) Wool wet with water, pH 10.8, with scales.

reducing the shrinkage of woollen goods 'Wet' chlorine and bromine treatments reduce the directional friction in alkaline media by decreasing both μ_1 and μ_2 to low values. Sulphuryl chloride treatment makes μ_2 approach μ_1 without greatly reducing the average friction. Alcoholic potash treatment increases both μ_1 and μ_2 in alkaline solution to approximately the same value.

In these preliminary experiments, horn was chosen as the second rubbing surface because it is chemically similar to wool and is more convenient to handle. A few experiments with wool fibre against wool fibre gave essentially the same results. Further work on this problem is continuing.

The above was written before I had an opportunity of seeing the recent communication by Whewell, Rigelhaupt and Selim⁴. These authors, using an 'angle of slip' method of measuring friction, have demonstrated changes in directional friction or scaliness. Our conclusions are in agreement, except that they find a decreased directional friction in alkaline solutions. This may be due to the fact that their determination was made at pH 9.24. I have previously reported that under some conditions a minimum rate of felting occurs at this pH with an increased rate at higher pH's⁵.

My thanks are due to Drs F. P. Bowden and D. Tabor for permission to use the facilities of the Lubricants and Bearings Section of the Council for Scientific and Industrial Research, and to Dr Tabor for help in discussion.

Radioactivity of the Neutron

THE mass of the neutron (1.00893 m μ) is about 0.8 Mev greater than that of the hydrogen atom (1.00813 m μ). We should expect that, from Fermi's theory, the neutron would be β^- -radioactive with a half-life period of about three hours, if the transition is not 'forbidden'. The fact that this radioactivity has never been actually observed is attributed to the extremely short life of the capture of the neutron by nuclei through which the neutron is passing (about 1.7×10^{-4} sec in paraffin). We here propose a method which may be capable of detecting the decay of the neutron.

Let a strong source of neutrons be put near a paraffin block, and let the neutrons, after being slowed down by paraffin, be incident on a vessel containing partly liquid heavy hydrogen. Since the neutron capture cross-section ($\sigma_c = 2 \times 10^{-28}$ cm²)¹ in the deuteron of the deuterium is only about one-thousandth of that of the nuclei in paraffin, we should expect the capture life-time for the slow neutrons of the former to be about one second. Within this time there is a measurable probability of the decay of the neutron. Thus the vessel containing liquid heavy

hydrogen, being exposed to slow neutrons for a certain time, must also contain hydrogen as the decay product of neutrons. The presence of these hydrogen atoms may be detected spectroscopically.

It may also be mentioned that the use of liquid helium instead of liquid heavy hydrogen would probably give better results, because the value of σ_c for neutrons in helium is probably smaller than in deuterium, although there is no experimental evidence for this up to the present.

A Simple Calculation of the Perihelion of Mercury from the Principle of Equivalence

IT is known that first-order phenomena described in the general theory of relativity can be deduced from the principle of equivalence. The present note serves as an illustration.

The principle of equivalence demands that the length along the field direction be deviated, to the first order of approximation, in the ratio $dr/(1 + \lambda/r)dr$, where λ is GM/C^2 , and that the time, dt , be modified into the expression $(1 + \lambda/r)^{-1}dt$. But the length normal to the field direction undergoes no change.

Hence the kinetic energy is expressible in the form $\frac{1}{2}(\beta^2 r^2 + \beta^2 \dot{\theta}^2 r^2)$ and the Lagrangian is accordingly $\frac{1}{2}(\beta^4 r^2 + \beta^2 \dot{\theta}^2 r^2) - V(r)$, where $V(r) = -GM/r$, $\beta = (1 + \lambda/r)$.

Now the equation of motion of a test body is

$$\frac{d}{dt}(\beta^4 r) - \beta^2 r \dot{\theta}^2 - 2r^2 \frac{\partial \beta}{\partial r} - r^2 \dot{\theta}^2 \frac{\partial \beta}{\partial r} + \frac{\partial V}{\partial r} = 0, \quad (1)$$

$$\beta^2 r^2 \dot{\theta} = h (= \text{const.}), \quad (2)$$

where β denotes $(1 + \lambda/r)$.

Retaining only the first order of λ , we have from (1) and (2):

$$-\frac{h^2}{r^2 \beta^2} \frac{d}{d\theta} \beta^2 \frac{d\mu}{d\theta} - \frac{h^2}{\beta^2 r^2} \mu = -GM\mu^2 - h^2 \mu^4 \lambda + 2r \frac{\partial \beta}{\partial r},$$

$$\text{or } \frac{d}{d\theta} \beta^2 \frac{d\mu}{d\theta} + \mu = \frac{GM}{h^2} \beta^2 + \lambda \mu^2 - 2 \frac{r^2 r^2}{h^2} \frac{\partial \beta}{\partial r}.$$

$$\text{But } \frac{d}{d\theta} \beta^2 \frac{d\mu}{d\theta} = \beta^2 \frac{d^2 \mu}{d\theta^2} - 2 \frac{r^2 r^2}{h^2} \frac{d\beta}{dr},$$

$$\text{hence } \frac{d^2 \mu}{d\theta^2} + \beta^{-2} \mu = \frac{GM}{h^2} + \lambda \mu^2,$$

$$\text{or } \frac{d^2 \mu}{d\theta^2} + \mu = \frac{GM}{h^2} + 3\lambda \mu^2$$

This is the same equation as that obtained from Schwarzschild's solution and the geodesic equation of a test body.

Spectrophotometric Determination of Vitamin A in Fish Oils

THE purpose of this note is to show that when the vitamin A content of a fish oil has been determined spectroscopically, the result should be expressed in mgm vitamin A per gm of oil $E_{1\text{ cm}}^{1\text{ per cent } 328\text{ m}\mu}$ could also be stated. In this laboratory we have had experience of the confusion that is rife in commercial transactions and investigational surveys when the results of the spectroscopic estimation of vitamin A in fish oils are expressed in IU/gm , and we seek the co-operation of chemists in the removal of this source of confusion. $E_{1\text{ cm}}^{1\text{ per cent } 328\text{ m}\mu}$ (hereinafter referred to for short as the extinction E) is a physical property of an oil which can be measured to an accuracy of 2 per cent on a suitable ultra-violet spectrophotometer. For the estimation of vitamin A, extinction is taken as proportional to the concentration of vitamin A. The use of the extinction to express vitamin A content has the advantage of unequivocal meaning for the chemist, but does not convey to dealers or consumers a clear indication of the concentration of vitamin A in the oil. A 'conversion factor' by which the extinction is multiplied to give the vitamin A content in IU/gm has been used in an attempt to overcome this difficulty. The attempt has failed because researchers and industrial laboratories in different countries use widely different 'conversion factors' ranging within the range of 1400 to 3000. Thus the British Pharmacopoeia uses the factor 1600, Morton¹ states "In the U.S.A. the 'conversion factor' of 2150 is commonly used." Baxter and Robeson² find values between 2350 and 3160 depending on the conditions, and a recent determination by the Advisory Committee to the British Pharmacopoeia reported by Mead³ gives the value 1740 as the best value for 'conversion factor'. The reasons for this unfortunate situation are discussed by Morton¹ and Hume⁴; the result is that the vitamin A content of oils from different sources cannot be deduced from the potency in IU/gm stated on the labels of the containers—a situation which causes mistakes and admits of misrepresentation in commercial dealings. A solution to the problem of clearly stating the vitamin A content is obtained if the extinction is multiplied by a factor to give the result in mgm vitamin A per gm of oil. Such a factor is known to

an accuracy of ± 3 per cent, which is within the error normally expected in the spectroscopic assay of fish oils. The factor required to convert E oil to

mgm vitamin A per gm. oil is $\frac{1000}{E_{\text{pure vit A}}}$

Measurements of $E_{\text{pure vit A}}$ which have been recorded in the literature since 1933 are noted in Table 1

TABLE 1 EXTINCTION (AT THE MAX NEAR 328 M μ) OF VITAMIN A ALCOHOL IN ETHYL ALCOHOL

Date	$E_{1\text{ cm}}^{1\text{ per cent}}$	Notes on sample	Ref
1933	1600	Non-crystalline concentrate prepared by molecular distillation	4
1933	1700	Non-crystalline concentrate prepared by molecular distillation	5
1934	1600	Non-crystalline concentrate prepared by molecular distillation	6
1937	2100 falling to 1800 on standing	Crystalline, containing methyl alcohol of crystallization	7
1939	1800	Crystalline	8, 9
1942	1760 ± 21	Nine samples of crystals	2
	1780	One sample, checked photoelectrically by Zscheile, F.P. (3 determinations)	2

Recent values for E of pure vitamin A alcohol in ethyl alcohol are covered by the figure 1780 ± 50 . This figure should be used for the estimation of non-saponifiable extracts. In fish oils, vitamin A is present as an ester. From Table 2, which lists the effect of esterification and solvent, a reduction to 1750 ± 50 is indicated. This figure should be used when the estimation is performed without prior saponification of the oil.

The chief error in the spectroscopic assay is the presence of irrelevant absorption at 328 m μ . Some estimate of the extent of irrelevant absorption may be obtained by noting the shape of the absorption spectrum, but no precise method of eliminating this error is known. It is more serious for low- than for high-potency oils. Saponification removes most of the irrelevant absorption, but involves a loss of vitamin¹⁴. These sources of error make the spectroscopic estimation of vitamin A in fish oils less accurate than the 2 per cent error normally allowed in the measurement of extinction. An uncertainty of 3 per cent in the conversion factor does not, therefore, make it unacceptable. It is absurd to use a factor which commonly has an uncertainty of 30 per cent and in extreme cases almost 100 per cent, as has the factor used to convert the extinction to IU/gm .

TABLE 2 EFFECT OF SOLVENT AND ESTERIFICATION OF THE EXTINCTION OF VITAMIN A.

In the following table is given the ratio of the extinction of the ester in a given solvent to that of an equivalent amount of vitamin A alcohol in ethyl alcohol. The extinction of vitamin A alcohol in alcohol is taken as 1,780 for the purpose of this table. Irrelevant absorption has been subtracted where necessary.

Solvent	Vit A alcohol	Non-sap content	Palmitate	Fish oils	β -naphthoate	Anthraquinone 2-carboxylate	Acetate	Succinate
Alcohol	1.00	1.00 S	0.97 B	0.97	0.92 B			
Isopropyl alcohol	0.98 Z				0.995 M		0.97 B	0.80 B
Cyclohexane	0.93 Z	0.97 S		0.98 S	1.00 H	0.995 M		
	0.88 B	0.89 A			1.09 H (+ 10% arachis oil)			
Hexane	0.98 Z	0.97 S	0.94 Z(?)*		0.95 H (+ 100% " ")			
iso-octane	0.96 Z		0.98 Z(?)*					
Ether	1.03 Z	1.07 S	1.00 Z(?)*	1.09 S				
Chloroform	0.83 G	0.86 S		0.90 S				
		0.71 B						
Ethyl alcohol		1.03 Z						
Ethyl formate		0.96 Z						
Benzene		0.83 G						
Styrol ether		0.91 G						
		0.99 B						

* For the calculation of these ratios the assumption is made that

$$\frac{E_{\text{Palmitate}}}{E_{\text{Ether}}} = \frac{E_{\text{Vit. A alcohol}}}{E_{\text{Ether}}}$$

$$\frac{E_{\text{Palmitate}}}{E_{\text{Alcohol}}} = \frac{E_{\text{Vit. A alcohol}}}{E_{\text{Alcohol}}}$$

These ratios are deduced from the following authors: A, Adamson and Evers¹⁰, B, Baxter and Robeson², G, Gillam and El Ridi¹¹, H, Hume⁴, M, Mead, Underhill and Coward³, S, Smith¹², Z, Zscheile and Henry¹³.

We, therefore, urge that this practice be discontinued, and that results of the spectroscopic estimation of vitamin A in fish oils be expressed in mgm vitamin A per gm of oil. For the convenience of analysts, and as an indication of the basis of the estimation, $E_{1\text{ cm}}^{1\text{ percent}}$ 328 m μ should also be stated.

Apparatus for Measuring Mean Cell-Diameters in Blood Film

A VARIANT on the halometer for the measurement of mean cell-diameters in blood films was constructed recently in a laboratory in the Middle East. As it is easy to construct, very portable and independent of darkened room and electric battery, it may be of some interest.

The feature which makes the adjustment simple and sturdy but precise is a sliding scale which carries a diagonal slit across a slit cut in the end of a light-proofed box. Thus light can only enter the box where the two slits intersect, and as the slide-scale is moved across the slit in the end of the box, this point of entry is seen to move along the end of the box at a speed governed by the angle of the diagonal slit in the slide-scale. At a suitable angle the adjustment can be made as fine as is desired. The use of a mirror inside the box provides a companion to this point of light in the box, moving in the opposite direction. The pair gives the two required diffraction patterns the proper juxtaposition of which gives the measurement reading on the scale.

The apparatus consists of a light-proofed box (9 in. $\times$ 3 in. $\times$ 1 in., a common size of tin here was found to be very convenient), a microscope slide (when blackened on one side to obviate double reflexion this makes an excellent mirror), a rectangular sliding piece as wide as the box (made to fit in or on the lid of the box when not in use, its sides should not wear too easily).

A slit S is made along most of the length one end of the box. In the top and bottom just behind this end, slots were cut to fit the slide-scale piece, so that when this is in position it completely prevents light from entering the box through the slit. A smooth microscope slide M was painted black on one side and fitted to the narrow side of the box reaching to within $\frac{1}{4}$ in. of the other end. In the end near the mirror a round viewing-hole V 6 mm across with the nearest edge 2 mm above the plane of the mirror was cut. Slots suitable to take the blood films were made in the top and bottom just behind the viewing-hole. The slot in the slide-piece was cut at a small angle to the length of the rectangle, but sufficient to give a range of movement to the point of entry of the light from 2 cm to 7 cm above the plane of the mirror. It is convenient to make the length of this piece such as to fit in or on to the end of the instrument. A curved spring strip to steady the slide in its slots may be considered necessary to eliminate variations in the readings. The measurements gave a range of reading from 5 to 11 microns. The inside of the box was blackened to exclude stray reflexions with their extra haloes.

Calibration can be done in many ways. The principle of the halometer relates the angle 2θ of separation of the two diffraction patterns to the predominant cell-diameter M according to the relation:

$$\sin \theta = N/lM,$$

where l is wave length of light used (usually 0.6 microns, in the middle of the red), N is order of reflection from centre of system (usually 2).

It is required to mark the positions of the slide-scale where the measurement of this angle corresponds to various suitable values of M . It is convenient to make the marks where the scale enters the box, the viewing-hole side of it. In this manner it is possible to observe the diffraction patterns with one eye while watching the reading with the other.

A suitable method of measuring the required angle accurately is to place the instrument on a table in a dark room with the slide-scale projected over the end of the table and the slit illuminated with bright diffuse light, for example, a 'pearl' bulb. The instrument should always be used with a diffuse source of light such as a lighted wall, daylight or 'pearl' bulb, as the light entering the box has to illuminate the viewing-hole directly and via the mirror simultaneously. With the instrument in the above position, a pin is placed vertically in the box intended for the blood films centrally to the viewing-hole. Two shadows of the pin are now outlined on the viewing-hole, and can be received on a screen or better still a metre rule, which should be placed at right angles to the line from the pin to the point between the two shadows. As the angle between the rays striking the pin is the same as the angle between the shadows thrown by them, the angle of separation between the two lights at the pin can be measured. In fact, the ratio between half the distance between the shadows on the screen and the distance from the rule to the pin is the tangent of the angle θ the sine of which is given by equation (1). Putting in the usual figures, we then write:

$$\text{Half distance between shadows} = \text{distance of rule from pin} \times \sin^{-1} 1.3$$

A table according to these figures is appended. The first column gives the reading for the predominant cell-diameter and the second gives

oper separation of the shadows on a rule at 100 cm in the pm

Cell-meter (microns)	Distance between shadows at 100 cm	Cell-diameter (microns)	Distance between shadows at 100 cm
4	69.4 cm	8½	31.0 cm
4½	62.5 "	9	29.3 "
5	54.3 "	9½	27.9 "
5½	49.0 "	10	26.4 "
6	44.7 "	10½	25.2 "
6½	40.9 "	11	24.0 "
7	38.1 "	11½	22.9 "
7½	34.9 "	12	22.0 "
8	33.2 "		

The technique is insert a suitable blood film and, mounting the instrument at a diffuse source of light, adjust the separation of the coloured rings until a second red rings in each system touch, and then read off on the scale. It is important that the film well covered to give a bright spectrum, but there could not be much overlap as the reading represents a predominant diameter of object on the slide (not an arithmetic mean). Two or three films should be examined as a check, approaching the end point on each side in each case. The degree of anisotropy is represented by the spread of the component spectra, that is, of the spread between the outer red and the smaller cells and the inner violet of the larger cells. In rare cases of anaemia with high degree of isocytosis the method is completely vitiated by clumping.

Sorption of Fumigants

WORK recently published by Lubatti¹ and by Winteringham² and experiments still in progress in the Imperial College seem to give some insight into the mechanism of the sorption of organic vapours, and as fumigants, on wheat.

Fumigants are sorbed by wheat very slowly. Three main factors are involved, (a) permeability of the seed coats, (b) diffusion and sorption in the endosperm, (c) chemical reactions which may take place in the tissues of the grains. The seed coats form a continuous envelope relatively impervious to gases, and they appear to be the main factor controlling sorption. In wheat which has been deprived by rationing of the seed coats, sorption appears to be of the same order as that in ground wheat.

The investigations of Barrer and Rideal³ and those of Wicke⁴ have established that in certain sorbents the rate of sorption is governed by the laws of diffusion. This is true in wheat with vapours which do not undergo a chemical decomposition or are only slightly reactive. Examples of such vapours are those of ethylene dichloride and hydrogen cyanide. Equilibrium with these is substantially reached in 15–20 days, and the experimental curves follow closely those calculated from Fick's law.

The forces which retain ethylene dichloride and hydrogen cyanide in wheat are predominantly physical (van der Waals). Accordingly, sorption increases with increase in temperature. It has also been found that the amount of fumigant sorbed is approximately the same at any time-concentration product, whether the concentration is kept constant or allowed to fall, provided that the average concentrations are the same.

Other vapours, such as those of ethylene oxide, react with the constituents of the wheat grains. The

reaction does not usually take place with one specific chemical compound. Many constituents of the tissues take part in the process, in which enzymic action may also assist. The rate of decomposition of the fumigant in the course of these reactions is apparently unimolecular. This may be due to the slowest process being diffusion through the tissues of the grain. The analogy between diffusion through polymers and unimolecular reactions has been pointed out by Barrer⁵. When sorption of the vapour is accompanied by chemical reaction, equilibrium is not approached even after several days. The curve representing the rate of sorption results from the superposition of two or more curves. With ethylene oxide there is a definite curvature towards the time axis during the first twenty-four hours, while physical forces are predominant, but later the curves straighten out and rise rapidly with time as the chemical action proceeds. It is during this period that the rate of diffusion through the tissues is probably the limiting factor. It would appear that these complex changes cannot be represented by mathematical expressions which would apply to more than one system.

With chemically active vapours, sorption increases with an increase in temperature. The time-sorption curve, calculated from experiments carried out with falling concentration, gives lower values than those obtained in experiments performed at an equivalent even concentration. Benton's work⁶ has shown that the velocity of chemical reactions at constant volume is not the same as that occurring in flow systems.

The sorption isotherms at a steady concentration, within the range of concentrations examined, appear to be rectilinear. As equilibrium is not rapidly reached, the so-called isotherms must be represented by a family of rectilinear curves arranged fanwise, the slope of the curves increasing with time. There appears to be a striking analogy between sorption by wheat and permeation through membranes. The work of Daynes⁷, Barrer⁸ and others has shown that the rate of activated diffusion of gases through membranes of organic polymers is linearly related to the difference of pressure established between the surfaces of the membrane.

An increase of the moisture contents of wheat brings about an increase of sorption with all the fumigants studied. This also may be connected with changes of permeability and structural rearrangements in the tissues of the wheat grain. Moisture content is a factor as important as time, concentration of vapour or temperature. A clearer view of the sorption of vapours by wheat is obtained when the 'isohydrotherms' are represented by tridimensional graphs showing the amount of vapour taken up against the changes of concentration and time.

A fuller account of the experiments referred to in this letter and the conclusions which can be drawn from them will be published elsewhere.

Effects of Sodium Thiocyanate on the Development of Amphibia

In previous work it has been shown that the notochord of embryos of *Rana esculenta* L., which from the late blastula stage onwards have been kept in solutions of 0.5–1 per cent sodium thiocyanate for 12–48 hr., appear hyperdeveloped in comparison with the controls¹. The same effect can be observed in embryos of the axolotl of *Amblystoma tigrinum* Green (= *A. mexicanum* Cope) and likewise in lampreys (*Petromyzon* [= *Lampetra*] *planeri* Bl.). A similar effect occurs under the influence of sodium iodide, vital dyes (pyocyanin, methylene-blue) and parantrophol². Some details of the alterations in development produced by sodium thiocyanate are given below.

The hyperdevelopment of the notochord characteristic of the influence of sodium thiocyanate becomes evident through enlargement of the area of cross-section of the notochord. Often, especially when the experimental larvae are shorter than the controls, the notochord folds up. In these larvae the notochord is longer than the body. From a comparative estimate of the volume of the notochord one finds, for example, in a larva of *Rana esculenta* (Fig. 2) originating from a blastula kept in 0.5 per cent solution of NaSCN $2H_2O$ for 48 hr., a volume of $86 \times 10^6 \mu^3$ as against $48.5 \times 10^6 \mu^3$ in the control (Fig. 1). This increase in volume is due to an increase in the number of cells already present in the rudiment of the notochord. In fact, as soon as the notochord is well defined, we have counted 1,561 cell-nuclei in the notochord of an embryo kept for 24 hr. in 0.5 per cent solution of sodium thiocyanate as against 1,090 in the control. When treated after neurulation, but before the tail-bud stage, one obtains larvae with a notochord which is enlarged in the tail, but normal in the trunk.

Parallel to the increase in the dimensions of the notochord are phenomena of hyperevocation. In several embryos a large mass of cells is formed which occupies the roof of the encephalic vesicles from the posterior part of the middle-brain to the hind-brain. This mass in some cases reaches the spinal cord. The cells of this mass in part degenerate, the rest form a ganglion lying in the median line in the roof of the fourth ventricle. The cross-section of the myelencephalon of these embryos is larger, and the lumen of the fourth ventricle may be obliterated by the growth of this ganglion.

All these alterations seem to be the reverse of those produced by the action of lithium chloride, which causes an inhibition of the development of the notochord and of the prechordal plate and thus a hypoevocation, namely, cyclopia³. Experiments were made in order to determine what kind of substances are capable of producing cyclopia in embryos of the frog and axolotl. These were found to be substances which precipitate proteins. The stronger they are in Hofmeister's series, the more readily do they produce cyclopia⁴. Sodium thiocyanate and sodium iodide, which produce monsters with hyperdeveloped notochords and hyperevocation, inhibit protein precipitation. Sodium thiocyanate, which has the greater effect, is the more inhibitory according to Hofmeister's series. The vital dyes and parantrophol, which cause an increase in respiration, have the same action as the inhibitory substances. This shows itself in various phenomena of embryonic development. One can obtain 'animalization' of the

Fig 1

Fig 2

FIGS 1 AND 2. RECONSTRUCTIONS OF THE NOTOCHORD AND OF THE NERVOUS SYSTEM AS SEEN FROM THE VENTRAL SIDE. (1) OF THE CONTROL LARVA, (2) OF A LARVA WHICH AS A LATE BLASTULA WAS KEPT FOR 48 HR. IN 0.5 PER CENT SOLUTION OF NaSCN $2H_2O$. A, LEVEL OF THE ANUS, A O, OTOCYST, E, EYE-OUT, Hb, HIND-BRAIN, Nch, NOTOCHORD, OI, OLFACTORY ORGAN ($\times 17$).

embryos of echinoderms both with sodium thiocyanate and sodium iodide⁵ and also, though to lesser extent, with the vital dyes or parantrophol. Ventral explantations of young gastrulae of Amphibia show neural evocation, whether cultured in Holtfreter's liquid containing sodium thiocyanate⁶ or vital dye⁶. In these experiments sodium thiocyanate is more active than methylene-blue⁷.

The similarity of action of the vital dyes and sodium thiocyanate in these experiments is not yet clear.

Swimming of *Monas stigmatica*

RECENTLY it was discovered at Plymouth that *Monas stigmatica*, E. G. Pringsheim, which is a small gellate organism with a length of 6μ , was, under proper conditions, capable of traversing a length 260μ in a second. Thus the organism has a stative speed of more than forty, or in other words traverses forty times its own length in a second, and on this simple calculation the organism has a stative speed which is twice that of the most modern 'Spitfire' and a thousand times that of a modern destroyer.

The principle by which this high speed is attained is that of the rotating inclined plane or the propeller, and since these flagellate organisms represent what probably the most primitive of all free-swimming organisms it indicates that the principle of the rotating inclined plane or the propeller has existed on earth ever since living organism first existed near the surface of the ocean, which was probably two or three hundred million years ago. It was not, however, until the year 1842 that the Admiralty owned a battleship driven by a propeller.

Monas stigmatica WITH ITS TWO FLAGELLA. DIAGRAMMATIC

Waves pass along the long flagellum, from base to tip, in a spiral manner with an increase in velocity and amplitude. The force generated is transmitted to the surface of the cell at A. This causes the organism to rotate and gyrate about the axis D (the edge B going below the surface of the paper and C being raised above it). Thus the organism is converted into a rotating inclined plane and moves forward more or less in the direction indicated by arrow E. The very short flagellum F appears to act as a guiding or sensory organ during normal swimming.

Citadel Hill, Plymouth

Porphyrim Formation by Yeast

In a recent communication, Rimington¹ has described his investigations into the formation of porphyrins by autolysing yeast and by yeast press, in which he demonstrated an increase in coproporphyrin in a cell-free medium prepared from yeast.

In our experiments we first of all attempted to determine conditions under which yeast would produce maximum amounts of porphyrin pigments. To this end, fresh top-fermentation brewer's yeast was allowed to autolyse at $19-22^{\circ}\text{C}$ alone and with the addition of various substances which were considered

possible porphyrin precursors. The best yield of porphyrin was obtained, however, by addition of solid ammonium carbonate to the yeast cells, when a yield of ninety-five times the value from yeast alone was obtained.

TABLE 1. COPROPORPHYRIN FORMED BY YEAST AFTER ADDITION OF AMMONIUM CARBONATE
450 gm fresh top-fermentation brewer's yeast. Duration of experiment, 96 hours

Experiment	Coproporphyrin found ($\mu\text{gm/gm}$ fresh yeast)
Yeast alone	0.9
With 10 gm $(\text{NH}_4)_2\text{CO}_3$	85.5
„ 10 gm $(\text{NH}_4)_2\text{CO}_3$ + 2 gm KH_2PO_4 + 2 gm NaH_2PO_4	59.0
„ 10 gm $(\text{NH}_4)_2\text{CO}_3$ + 30 ml amyl alcohol	43.8

When the rate of porphyrin production was studied under these conditions, it was observed that a rapid linear rise until approximately 60 hours was followed by a very sharp fall after 90 hours until porphyrin had almost disappeared from the medium. During the first period, the yeast cells were very active and the disappearance of porphyrin coincided with the onset of true autolysis of the cells.

TABLE 2. RATE OF COPROPORPHYRIN FORMATION BY YEAST AFTER ADDITION OF AMMONIUM CARBONATE
250 gm fresh yeast, 5 gm $(\text{NH}_4)_2\text{CO}_3$ added, kept at $19-22^{\circ}\text{C}$

Duration of experiment (hr)	Coproporphyrin found ($\mu\text{gm/gm}$ fresh yeast)	Relative amounts of isomers present ($\mu\text{gm/gm}$ yeast)		
		Copro III	Copro I	Copro III / Copro I
0	3.65			
6	13.2			
22	27.6	0.10	12.5	0.008
43	53.2	24.5	6.6	3.7
66.5	56.7	34.6	3.2	10.8
90.5	47.0	21.2	5.80	3.66
114	7.1			
162	3.2			
186	5.1	1.2	2.2	0.54
234	19.1			

The difference between the total coproporphyrin value and the sum of the two isomers is due to losses incurred in methylation and separation of the pure methyl esters.

When glucose, mannitol and other sugars were added to the yeast, it was observed that with prolonged activity of the yeast the porphyrin content also remained at a high level.

TABLE 3. COPROPORPHYRIN FORMATION BY YEAST AFTER ADDITION OF AMMONIUM CARBONATE AND SUGARS
250 gm fresh yeast + $(\text{NH}_4)_2\text{CO}_3$ + sugar

Experiment	Coproporphyrin found ($\mu\text{gm/gm}$ fresh yeast)			Relative amounts of isomers present after 168 hours ($\mu\text{gm/gm}$ fresh yeast)		
	24 hr	48 hr	168 hr	Copro III	Copro I	Copro III / Copro I
5 gm $(\text{NH}_4)_2\text{CO}_3$ + 5 gm glucose	16.8	24.0	60.0	0.0	33.2	0.0
5 gm $(\text{NH}_4)_2\text{CO}_3$ + 10 gm glucose	15.6	16.8	84.0	0.0	64.0	0.0
4.4 gm $(\text{NH}_4)_2\text{CO}_3$ + 25 gm glucose	16.8	5.7	84.0	9.4	46.0	0.2
5 gm $(\text{NH}_4)_2\text{CO}_3$ + 25 gm mannitol	9.3	18.7	100.8	1.5	67.2	0.02

Brewer's wort

284 (72 hr)

As a result of these and other experiments under varying conditions, it is concluded that the maximum formation of porphyrins by yeast is associated with great cellular activity, and the amounts here found are much greater than those resulting by changes occurring after death of the cells.

Intracellular poisons, such as sodium fluoride and even 1 per cent toluene, caused a rapid decline in the porphyrin content by slowing down the metabolism. Samples of brewer's wort collected at intervals during fermentation exhibited the same changes as with ammonium carbonate alone, with the accumulation of 284 μgm porphyrin per gram of original yeast at the end of the active fermentation period (72 hr), but all this pigment was used up in the ensuing forty-eight hours.

Fractionation of the porphyrins showed that traces only of proto- and deuterio-porphyrins were present, insufficient for identification of isomers. Coproporphyrin comprised in most instances a mixture of isomers I and III which were determined by ultra-violet fluorimetry and identified by crystallography and melting point of the methyl esters. The relative proportions of the two isomers varied within wide limits, it is interesting to see that coproporphyrin I predominates when sufficient carbohydrate for respiration is present, but in conditions of carbohydrate starvation (after 66 hours, Table 2) coproporphyrin III appears in large amounts, and is responsible for practically all the porphyrin present under these conditions. Thus the isomers III or I may predominate in yeast according to the nature of the nutrient medium.

Further investigations are being carried out to determine if, and how, these changes are related to cytochrome synthesis and rate of respiration.

Geology of the Punjab Salt Range

WITH reference to Sir Cyril Fox's interesting article under the above heading¹, I wish to make certain comments. I think that nobody maintains that the Kohat-Potwar Saline Series is of post-Eocene age. As Prof Sahni says², his "fossil evidence is consistent with any geological age from the Lower Tertiary to the recent. But since on stratigraphical grounds the Saline Series cannot be younger than early Tertiary, the conclusion is that it is of Eocene age." I have shown³ that the latest marine beds of that region are of Upper Khirthar (Auversian) age, so there were apparently no marine waters to desiccate, in that region, after the Eocene.

Again, aridity alone seems to be stressed when discussing the production of thick salt deposits. Thus Sir Cyril says (p. 259) that "an arid period almost certainly prevailed in early Cambrian or pre-Cambrian times, which, according to Mr Geo, was soon after the rock-salt deposits had formed in the Punjab area", and he adds that "there is little such evidence in support of an Eocene age for these deposits". But the main essentials for producing thick salt deposits are topographical rather than climatical. So far as climate is concerned, it is only necessary that evaporation should dispose of all

waters in, or entering, the area concerned, but the production of an excessive accumulation of salt is not a simple matter—it demands rare topographical conditions like, for example, those now existing in the Dead Sea region, or those on the eastern border of the Caspian Sea (Karaboghaz Gulf), etc.⁴ Nobody has yet attempted to show that the pre-Cambrian topography of the Kohat-Potwar region was of or of these exceptional kinds.

On the other hand, I have shown⁵ that topographical conditions of such a kind did apparently exist, in that region, in Lower Chharat (basal Khirthar, or earliest Middle Eocene) times. So I must point out that Dr West's summary of papers to which Sir Cyril refers (p. 258), is incomplete in this respect. For it was not until 1936 that I finished surveying the Eocene beds of the Kohat district, and realized that Lakki (Lower Eocene) elements did appear from below upwards to the west, and do not exist in Waziristan.⁷ French geologists, working from the opposite (Afghanistan) side, soon afterwards made corresponding observations⁸, showing that what I call a "Waziristan ridge" rose at the close of Ranikot (Palaeocene) times. The emergence of this ridge must have greatly reduced the marine connexions of the Kohat-Potwar basin, which were by more fully severed at the close of Lakki times.⁹ It is obvious that along the southern borders of the basin—and especially at their western extremity where spasmodic marine incursions still occurred even in Lower Chharat times¹⁰—topographical conditions would have favoured the production of large accumulations of salt (waters were, in fact, trapped and trapped in such a manner as to satisfy the theory of G. Bischof and C. Ochsennius regarding the way of forming thick salt deposits, cf F. W. Clark as above⁴). Thus I briefly indicated in my last letter the main point of which is apparently missed by those who refer to it¹¹ only to stress Mr Gee's change of mind as to whether the fossils which I identified in him had or had not, been found by him *in situ*.

To discuss further points would unduly extend this letter, so I merely emphasize, here, the need for considering the topographical essentials for producing thick salt deposits. Whether or not suitable conditions existed in pre-Cambrian times (a matter which seems never to have been worked out, and may not be capable of demonstration) I can scarcely agree that they did not exist in Eocene times. The Eocene is the one period when known structural evidence indicates that they did exist.

'Rubber Acid' Damage in Fire Hoses

READERS of the article on the above subject by Jansen, Bunker and Adams¹ may be interested in my experience when called upon to suggest means of preventing or delaying the relatively rapid deterioration of war-time fire hoses.

It was early realized that this deterioration was of bacterial origin and associated with the formation of sulphuric acid, although no attempt was made to isolate or identify the organisms concerned. On the strength of the information available, however, I decided to try the effect of sterilizing the hose after use. Calcium hypochlorite bleach liquor was therefore added to a static water tank so as to produce a residual free chlorine content of 5-10 p.p.m. (o-tolidine test). The contents of the tank were pumped through the hose (by means of a trailer pump) and back again to the tank. This circulation was continued for about 15 min., after which the free chlorine had fallen to 1 p.p.m. or less. The hose was then drained and stored.

There was no evidence of damage due to the chlorine. Comparative tests with lengths of similar hose which had been treated as described above, using chlorinated and unchlorinated water, showed that the life of the former was 50-100 per cent longer than that of the latter. The treatment had little or no beneficial effect on pre-war hose, which had a longer life in the untreated state. The treatment could, of course, be applied each time the hose is used, before it is stored.

A Colonial Scientific Service

I AM much interested in the idea of a Colonial biological service, as an independent organization or part of a wider Colonial scientific service, that my friend Mr K. H. Chapman has recently put forward¹.

What impressed me most often about the work of a scientific specialist serving overseas under the present system is the actual isolation in which his work is carried out, and the acute sense of this isolation which he often develops. One deleterious effect of this is that it may restrict research to problems for which facilities are available, and which may be relatively less important and perhaps not those for which the specialist's individual aptitudes are best fitted.

Many particular problems would be more rapidly solved if either additional specialist help could be made temporarily available, or the worker and his problem could be transferred to some laboratory or research institute in Great Britain. Some specialists manage to arrange the latter either by persuading their superiors to grant special leave of absence to work at home or by sacrificing part of their normal leave to the work. Admirable as the spirit of the latter solution is, it is wrong in principle, and the former may be dependent on sympathetic consideration by a non-specialist superior. Some of Mr Chapman's remarks are relevant to this last point.

A most important feature of a Colonial biological service with a centralized headquarters would be, as Mr Chapman points out, the possibility of concentrating selected specialists as a team on any specific problem and preventing overlap of unco-ordinated

individual efforts in different regions. An example of this kind of arrangement is the work of the Anti-Locust Centre in London², in connexion with which workers, scattered over a huge area, are all carrying out pieces of work in a pattern designed to solve the general problem of the locust pest. This particular project has drawn personnel from many sources not always immediately available in peace-time, but this only shows the resources which a centralized service might draw upon.

That biologists who intend to spend most of their active lives attached to research and teaching institutions in Britain would benefit from a temporary seconding to overseas work can scarcely be doubted. A centralized service would enable such secondings to be made in the most profitable way.

Another example is the work of the International Health Division of the Rockefeller Foundation. The Foundation's annual reports show how a cadre of experts has been moulded and remoulded to form the basis of a series of teams that have been sent all over the world to tackle problems in tropical medicine, especially those relating to insect-borne disease, a method yielding some quite spectacular results^{3,4}.

Whether a centralized service such as Mr Chapman has suggested would, as he seems to hope, equalize the inequalities of status that he has found between medical and veterinary practitioners and biological specialists is difficult to know. Surely the solution of this problem lies in the direction of making biology an organized profession. Chemists and physicists are moving in this direction with their respective institutes. If medical men, veterinarians, chemists, physicists, accountants, librarians and others can do this, surely it would not be beyond the wit of biologists to do likewise.

Wax Pencils for Writing on Cold Wet Glassware

THE wax pencils supplied commercially for writing on glass are unsatisfactory when the glass is cold, or covered with a film of moisture.

Pencils which will write on cold wet glass can, however, be prepared by the addition of 5-10 per cent of a detergent, preferably cationic, to the wax and pigment mixture forming the pencil 'lead'. Of the many possible formulæ, the following can readily be made up in the laboratory without special skill.

Hard paraffin wax (m.p. 65° C)	100 gm
Beeswax	20 "
'Vaseline'	20 "
C.T.A.B. (Cetyl trimethyl ammonium bromide)	10 "
Fat soluble dyestuff (for example, Sudan III)	0.5-1.0 "

The mixture is heated on a water bath and stirred until the waxes have melted and the dye and detergent dissolved. 20 gm of titanium oxide or other white pigment are then stirred in. The pencils are made by casting the mixture in sticks about 6 in long by $\frac{1}{8}$ in in diameter and wrapping in paper.

SOCIETY OF AGRICULTURAL BACTERIOLOGISTS

ANNUAL MEETING

THE Society of Agricultural Bacteriologists held its fifteenth annual meeting at Leeds during December 17-19. The papers and the discussions covered a much wider field than is implied by the Society's title, a tendency which has become increasingly apparent each year since the Society adopted a policy of opening its membership to workers in all branches of bacteriology. Dr W. T. Astbury gave an address on the electron microscope followed by a demonstration of the instrument.

A contribution to the subject of disinfection dealt with the fundamental processes leading to the death of bacteria. In this work *Bacterium coli* was used as the test organism and phenol as the disinfectant. Special precautions were taken to avoid environmental changes during the tests, the phenol being added to cultures of the organisms grown in a special apparatus designed to ensure stable conditions throughout the period of the experiment. The experiments covered a range of phenol concentration from 3.48 to 8.0 gm/l., and a temperature range of 20-42° C. The results obtained led to the conclusion that the logarithmic curve of disinfection is really only an approximation, due to the process of disinfection proceeding too rapidly in the early stages to be estimated. The true disinfection curve indicated a slow initial death-rate, followed by a rapid rise to a high value, the peak value was followed by a rapid and then by a slower decline, the death-rate becoming constant at the extreme end of the process of disinfection.

Starr's aniline blue medium for the detection of lipolytic organisms has been improved by staining the butterfat substrate with Waxolene Red 111S (ICI), which ensures optimum colour differentiation between lipolytic and non-lipolytic colonies. Tests on forty-four cultures of lipolytic and non-lipolytic bacteria showed the new medium to be equal in discriminating powers to the copper soap method while possessing the added advantage that colonies could be subcultured following differentiation. It gave less false-positives than tributurum agar. Details of its preparation were given.

A study of methods suitable for assessing the sterility of equipment used in dairy and food manufacturing operations has shown the value of swab methods for this purpose. Colony counts on swab solutions from surfaces were normally much higher at 32° C than at either 37° C or 22° C, especially in the case of plant used for raw milk, meat canning, and in the bakery. The results emphasized the desirability of incubating plates at more than one temperature, and indicated 32° C to be the temperature of choice when only one incubator was available. The predominating flora of swab solutions from the various types of plant examined was described, and the value of the swab technique in tracing the source of specific fault-producing organisms in large equipment was emphasized.

Since the adoption of the methylene blue test as an official method for the examination of heat-treated milk, increasing interest has been taken in the use of dye-reduction tests for this purpose. The results of various bacteriological methods of testing pasteurized milk were related to keeping quality in a study of 505 samples of pasteurized milk distributed by

twenty-seven dairies during a period of two months. Neither the colony count at 37° C, the methylene blue test, nor the resazurin test were suitable measures of keeping quality when applied the day of distribution, but the dye-reduction test proved suitable for detecting milk with a poor keeping quality, when the samples before test were stored at 18° C from 3 p.m. on the day of distribution until 10 a.m. the next morning. The value of the coliform test for the examination of pasteurized milk was also once more confirmed. A simple lagged water bath, utilizing mains water cooling, with thermostatically controlled electric heating, was used for maintaining a temperature of $18 \pm 1^\circ \text{C}$.

The examination of raw milk by the resazurin test continues to receive attention as a means of grading milk. The suitability of this test as a measure of keeping quality was assessed by comparison with the methylene blue test, the colony count and the titratable acidity, the results being subjected to statistical analysis.

In an attempt to explain occasional discrepancies between the results obtained by the resazurin and other tests on raw milk samples, the effect of pre-cultures and of cells on the reduction of the dye has been investigated. Pure cultures of bacteria were found to vary markedly in their power to reduce both resazurin and methylene blue, although the more active milk-souring organisms reduced the dye faster than organisms not possessing this property. *Streptococcus agalactiae* and *Bacillus subtilis* were notable exceptions, the former being a poor reducer and the latter reducing resazurin at an appreciable rate. Methods of measuring the relative reducing activity of cells and bacteria were discussed, and the difficulties emphasized. Neither the enzyme inhibitors used nor the temperature effects tried provided a satisfactory solution to the problem.

Theoretical consideration has been given to the possibility of developing a more rapid and equitable method for testing large numbers of raw milk samples. Since souring is the predominating cause of defects and difficulties in handling, it was assumed that measurement of the increase in acidity under standard conditions of storage was most likely to offer a solution. Of the three methods available, titratable acidity was considered too cumbersome for routine purposes, and conductivity measurements, though technically relatively simple, were not considered sufficiently sensitive measure of increase in acidity. It was eventually decided to depend on pH value determined with a glass electrode. A close relationship was found to exist between decrease in pH value and increase in titratable acidity.

The cleansing and sterilization of milk bottles and other surfaces in which the strength of detergent governs the efficiency of the processes is a problem of immense commercial importance. Titratable methods are normally used for estimating and controlling the strength of detergents, but a method involving a direct-reading meter has obvious advantages. Preliminary work indicated the suitability of a direct-reading conductivity meter, and the construction of an apparatus suitable for use in detergent solutions in dairy equipment was described. Owing to variations in the constituents of commercial detergents, calibration of the instrument was found to be necessary for each detergent. The method had the further disadvantage that it was less sensitive to changes in the concentration of sodium hydroxide.

ian't it was to those of other salts, although it was pointed out that the majority of commercial detergents consist largely of carbonates and phosphates. An extensive survey, covering the period 1930-44, of the incidence of *Mycobacterium tuberculosis* and *Mycobacterium avium* in herd bulk milk from individual farms in mid- and west-Wales was reported. Some figures for school supplies of pasteurized milk, for milk creamery skim milk, both raw and pasteurized, and for udder samples from suspected cows were also included. Reasons were advanced for the very low incidence of tubercle infection (0.74 per cent for 155 samples) in farm supplies. No tubercle bacilli were found in any of the twenty-eight samples of pasteurized milk supplied to schools, nor in the forty-eight samples of pasteurized bulk creamery milk examined. Of the sixty-six samples of raw milk creamery skim milk, 6.06 per cent contained tubercle bacilli, legislation prohibiting the turn of raw by-products to farms was considered essential for the development of areas of tubercle-free herds. A much higher proportion (8.91 per cent) of raw milk samples was found to be infected with *Mycobacterium avium*, designated supplies showing a higher incidence than milk from undesignated farms. No positive results were obtained with the pasteurized samples.

In a paper dealing with the spoilage of marine fish, the sources and types of bacteria responsible were discussed. The existence in marine bacteria isolated from fish of an enzyme system, triamine-oxidase, which is not generally present in similar bacteria from other sources, was suggested as a basis for differentiating the various species of marine bacteria. Changes in flora which occurred during a 21-day period of storage on ice were also studied. Although aerobes were not considered to be as important as anaerobes in causing spoilage, the types isolated were described, and the isolation of a new serological type non-pathogenic tetanus bacillus, Type X, was recorded.

With the demand for canned foods for use by the Armed Forces in hot climates, new problems have had to be faced by the canning industry, since storage temperatures may be high enough to permit the germination and growth of spore-forming thermophilic organisms capable of causing spoilage. New methods of control have had to be introduced so as to reduce to a minimum the risk of infection before canning, as it is not always possible to increase the time or temperature of sterilization sufficiently to ensure destruction of the highly resistant thermophilic spores. Difficulty in sterilizing a mixture of meat and vegetable with a relatively high fat content was thought to be due to protection of the thermophiles by the fat. Cases of spoilage in canned vegetables are rare. Difficulty in canning potatoes late in the season was thought to be associated with the use of large tubers, which had to be cut before canning, the sterilization process being inadequate to kill spores at the centre when two cut surfaces came together again. In a paper dealing with the bacteriology of canned food, a novel method of canning was described. Difficulties in sterilization led to a proportion of spoiled cans. A gas-forming aerobic spore-former capable of utilizing nitrate as a source of oxygen, which was isolated from both spoiled and sound cans, was regarded as the causative agent, although other known factors were thought to play a part in the production of gas.

For several years, bacteriologists have necessarily

been concerned with the more pressing practical problems, but at this meeting a refreshing change was noticeable in that a few papers of a more fundamental character were included. A much happier blend resulted, which augurs well for the future of the Society.

Proceedings of the Society, containing full abstracts of the papers read, may be purchased from the Hon. Treasurer, Mr. L. J. Meanwell, United Dairies, Ltd., Ellesmere, Salop.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

IT was inevitable that the work of the London School of Hygiene and Tropical Medicine, which has exerted so profound an influence on the teaching and practice of tropical medicine by both British and other medical men, should have been radically affected by the War. The report of the School's work during 1943-44 shows how much its normal activities have been altered. Not only have thirty-six members of the staff been engaged on full-time war service, but also specific war problems have been studied at home, and the School has provided accommodation for members of the staff of the Medical Research Council and of the University of London, who are doing work of national importance. Nor have the School's buildings escaped war damage. Yet, during the year, it has been possible to give courses in tropical medicine to some five hundred Service medical officers and other special courses to 151 students. The acting dean, Prof. M. Greenwood, and the whole School are to be congratulated upon the year's work. It is gratifying to know that it has been possible to do, as well as war work, some fundamental research of a kind which is vital to the very existence of science, yet is, in the words of Prof. Greenwood, "slighted in wartime because the results may not be of immediate technological importance".

Prof. Greenwood refers to the difficulties which the School will have to face after the War, and he doubts whether national post-war needs will allow the School to resume normal teaching until, at the most optimistic estimate, the autumn of 1945-46, perhaps not until a year later. He suggests that the resumption of teaching will not be easy, for the returning staff will have lost touch with the normal problems of academic work and will have to teach a generation trained somewhat hurriedly and under difficulties.

The brief departmental reports indicate the effects of departures of staff for war work and also of the national value of the work which has been accomplished in spite of these losses. Thus the Department of Entomology has been much concerned with work on DDT, which was originally brought to the School by a representative of the Swiss firm which placed this remarkable insecticide at the disposal of the British and American Governments (see *Nature*, Nov. 11, 1944; p. 600). Methods of impregnating clothing with DDT for the control of human lice were devised, and this method of applying DDT is now general. The use of DDT for the control of the bedbug is also being studied. Much work has been done on fumigants and mosquito sprays, and a formula for the latter containing DDT has been generally adopted. The physical and chemical problems involved in the control of insects by means of sprays are also being investigated. This Depart-

ment has lost the services of Dr V B Wigglesworth, who has been appointed director of the Insect Physiology Unit of the Agricultural Research Council, but co-operation between these two departments continues. Dr Wigglesworth has studied the part played by waxes in maintaining the impermeability of the insect cuticle to water and has found that some chemically inert dusts abrade the wax and thus kill insects by causing them to dry up (see *Nature*, 153, 493, 154, 333 (1944)). His Unit is also studying the action of insecticides used as sheep dips against the sheep tick, *Ixodes ricinus*, the water relations of this tick and the physiology of the sheep blowfly, *Lucilia sericata*. Field trials of DDT as a sheep dip are also being made. The possible importance of work of this kind to all those who are concerned with world supplies of meat, wool and other animal products can scarcely be over-estimated.

The head of the Department of Biochemistry, Prof H Raistrick, has given much time to work with penicillin; he is honorary scientific adviser to the Ministry of Supply on penicillin production. This Department has also studied the deterioration of service equipment in the tropics due to the action of moulds and is searching for antibiotic substances of microbiological origin. Although *penicillium patulum*, prepared by the Department from *Penicillium patulum*, proved unable to control the common cold (see *Nature*, 154, 807, Dec 30, 1944), two other metabolic products of this mould have been isolated, namely, gentisic acid and the hitherto unknown gentisyl alcohol, the latter has been synthesized. A new antibacterial substance has been isolated from cultures of "a somewhat rare mould" which has not yet been identified with certainty, this substance appears to belong to a new type of organic compounds and its properties are being studied. Diplococcin, a new antibacterial substance formed by some strains of milk streptococci, has been isolated. It is probably, the report says, identical with a substance independently isolated at the National Dairy Research Institute, Shinfield, and described by A T R Mattick and A Hirsch (*Nature*, 154, 551, Oct 28, 1944). Mattick and Hirsch found that the substance isolated by them protects mice against strains of haemolytic streptococci virulent to mice and suggest that it may be useful for the treatment of bovine mastitis.

The appointment of Prof J M Macintosh to the University of London chair of public health assures the School of vigorous and able leadership. The Association of Industrial Medical Officers is using the School more and more as its headquarters. Among researches done at the School's Department of Industrial Physiology are those on the insulating properties of clothing materials, the important question of portable sources of light, such as reading lamps, the results of which study have been published in the *Transactions of the Illuminating Engineering Society*, and the dangers to health of industrial dusts, advice given on the working conditions in factories has brought benefit to many workers.

The Library of the School has been busier than ever. It has increased its stock of books and pamphlets, but has experienced the difficulty of obtaining American books which is the subject of an Annotation in the *Lancet* (217, Feb 17, 1945). The School also houses the Bureau of Hygiene and Tropical Diseases, the painstaking and indefatigable work of which, published in the pages of the *Tropical Diseases Bulletin*, the *Bulletin of Hygiene* and the *Bulletin of War Medicine*, makes available abstracts of the

medical literature of every country in the world. These abstracts are done by a panel of experts, whose experience adds a critical quality which is absent from many other publications of this kind.

The Institute of Agricultural Parasitology, directed by Prof R T Leiper, professor of helminthology at the School, has done much work at Winches Farm, St Albans, on the nematode parasites of valuable crops. A catalogue of more than six hundred species of helminths parasitic in birds of economic importance has also been compiled. A method has been devised for the identification of certain nematode species from the females alone, which should be of great value to parasitologists, and the nature and development of cestode hooks has been studied. It is at Winches Farm also that the work of that other valuable source of information, the Imperial Bureau of Agricultural Parasitology, is done.

Everyone will wish the School a speedy return to its normal activities when the completion of its work makes this possible.

RACIAL PROBLEMS IN AUSTRALIA

WITH the progress of civilization and the continued penetration by the white man into the domain of the coloured peoples, there comes the problem, ever increasing in intensity, of the contact and clash of conflicting customs. Men in the stone or iron age are caught up into the complicated machinery of the Western world, and the results are necessarily difficult to regulate and often disastrous to the simpler peoples.

The Anthropological Society of South Australia at its meeting in May 1944 held a conference arranged by the South Australian Division of the Australasian Association of Scientific Workers, during which there was a discussion on racial problems to which Prof J B Cleland contributed a valuable address. He pointed out that the Australian aborigines, contrary to popular belief, present a high order of intelligence and had they not settled in a country which provided very few amenities, they would probably by now have reached a much higher stage of civilization. "What could they do in a country boasting no animal life higher than the marsupial and practically cultivable plants? They were forced to remain nomads and with the arid conditions so frequent obtaining could make no permanent habitations."

Potentially, however, judging by a complex language and by the attainments of certain individuals, the Australian aborigine has a mental make-up appreciably below that of the white man, though he has specialized in a different direction. There is nothing to show that crosses between them and good class whites are likely to produce undesirable hybrid breeds, the fact that many half-castes are inferior being probably due to the low-class and often vicious white men of whom they are the offspring.

There have always been attempts to guide the aborigines into European ways, but these have heretofore led to rapid decline and death, owing in great part to lack of interest in living when removed from their native mode of life with its frequent ceremonies. It seems, in fact, impossible for the full-blooded natives to maintain themselves in a white community, and the only hope for them is to make the few places to which they can call their own as inaccessible as possible to the white man. There will naturally always be certain

venturous spirits who will roam away and, through contact with the whites, lose touch with the old. These newly detribalized men should be assisted to maintain themselves as respectable members of a community and to do suitable work, as much in a country as possible, on the cattle and sheep stations. They should be under some sort of supervision and be encouraged to keep up their tribal customs and corroborations.

The completely detribalized aborigines of long-standing separation from their own communities are more difficult problem, having mostly become banized and of mixed blood. Prof Cleland considers that they should not be segregated from the whites and regarded as inferiors, but should be educated to become good citizens and take their share of community life.

K RISHBETH

PREHISTORY IN THE CONGO*

THE prehistoric archaeology of the Congo is very little known. The researches of Dr Cabu were first published at the International Congress held in Brussels in 1935, but most of his discoveries are still unknown to the average prehistorian. Yet the Congo is probably a key area, linking as it does the north with the south of the African continent. The little bit of information on the subject which had come current among prehistorians concerned an alleged new culture, the Tumbrian, but now even this latter seems actually to be non-existent, and the history in question merely a *mélange* of early, middle and later stone age material, somewhat responding to the Sangoan of Uganda.

It is, therefore, of very great interest to have the studies as these under notice from the pens of prehistorians of the eminence of Profs Breuil and Riet Lowe. Alas, there are no illustrations. Both authors' articles are technical, and describe in detail the industries found at a number of stone age sites and their cultural affinities. An intriguing reference occurs at the end to discoveries of painted rock-shelter sites. The paintings are in red and conventionalized. Prof. van Riet Lowe also describes in detail the industries and compares them with those occurring in South Africa and in the Uganda-Kenya regions. He, too, claims that the Tumbrian consists of "advanced Acheul, La Micoque and Combe auenne bifaced tools (i.e., Fouresmith), ? proto-Stillbay, Sangoan picks, Stillbay points, Aterian and African bifaced points (including pedunculate ones), ground and polished axes and pottery", "a mixture". He also notes the occurrence of lithic tools. This reinforces the contention that this culture is not purely a South African product, but backs up Archdeacon Owen's finds of a Smithfield industry in western Kenya.

Quite obviously we shall have to await the end of the War for a full account of the prehistory of the Congo. But enough is here given to make it clear that this important area is likely to be critical in any general appreciation of the Stone Ages in Africa.

STRAY LOSSES IN SYNCHRONOUS ELECTRICAL MACHINERY

P. RICHARDSON, in a paper read before the Institution of Electrical Engineers in London recently, discusses the problem of eddy currents from the point of view of the effect of the physical arrangement of an alternator on the stray losses, and deals afterwards with the components of stray loss. Since the latter can be classified conveniently in accordance with their position in the alternator, the stray losses which occur in the stator are considered first.

It is shown how the arrangement of the end-windings influences the shape of the end leakage field and thus the intensity of loss in the adjacent metallic structures, and how the loss in the core-end-plate can be estimated. The effect of magnetic and non-magnetic shielding arrangements is discussed, together with details of their arrangement. Experiments in connexion with eddy-current losses in the stator end connexions are described. Consideration is given to the iron loss which occurs in the stator core under steady three-phase short-circuit conditions owing to the flux-wave shape, and the indications are that this provides at least a partial explanation of why the stray losses can be so appreciably greater on short-circuit than on load.

The stray losses in the rotor, generally grouped under the heading of rotor surface losses, are shown to be due to several effects, notably to the concentration of ampere-conductors in one slot and to the irregularities present in the stator magnetomotive force wave. Consideration is also given to the surface or pole-face losses resulting from the 'tufting' of flux under the stator teeth, which loss is experienced under conditions of no load and is normally measured with the stator iron loss. The factors affecting the surface losses are discussed, together with methods for reducing the losses to a minimum. An indication is given of the relationship between the stray losses at the ends and those located within the core-length of an alternator, together with a description of the effect of load conditions on each of the components of stray loss.

FORTHCOMING EVENTS

Saturday, May 12

INSTITUTION OF THE RUBBER INDUSTRY (MIDLAND SECTION) (at the Imperial Hotel, Birmingham), at 10 a.m. and 2 p.m.—Symposium on "The Physical and Chemical Breakdown of Rubber"

Monday, May 14

ASSOCIATION OF AUSTRIAN ENGINEERS, CHEMISTS AND SCIENTIFIC WORKERS IN GREAT BRITAIN (joint meeting with the ROYAL NETHERLAND INSTITUTE OF CIVIL ENGINEERS AND THE SOCIETY OF DANISH CIVIL ENGINEERS) (at the Institution of Structural Engineers, 11, Upper Belgrave Street, London, S.W.1), at 6.30 p.m.—Prof. K. W. Mautner "Extension Work on the Harbour of Dunkirk, 1930-1938" (Lantern Lecture)

Tuesday, May 15

ROYAL SOCIETY OF ARTS (DOMINIONS AND COLONIES SECTION) (joint meeting with the ROYAL AFRICAN SOCIETY) (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Mr Malcolm Guthrie "East Africa's Reactions to European Culture"

INSTITUTION OF ELECTRICAL ENGINEERS (RADIO SECTION) (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Discussion on "The Characteristics of Luminescent Materials for Cathode Ray Tubes" (to be opened by Mr C. G. A. Hill)

Wednesday, May 16

RELIEF AND REHABILITATION IN EUROPE

A MAJOR problem now before the United Nations is the provision of food, clothing, medical supplies and other necessities of life in the newly liberated countries of Europe, so that they may be able to carry on until long-range plans for rehabilitation begin to take effect. The debate in the House of Commons on March 28 on supplies for Europe fairly reflected the growing concern which has been, and still is, felt in Great Britain. The seriousness of this question of relief and rehabilitation as a reconstruction measure has repeatedly been emphasized, in such books as Mr Bryant's "Unfinished Victory" even five years ago, in Colonel Bonsal's recently published diary of the peace conference following the War of 1914-18 entitled "Unfinished Business", and in such scientific studies as those of the Royal Institute of International Affairs on "Medical Relief in Europe" and "Relief and Reconstruction in Europe the First Steps". The picture of Berlin and the mind of Germany as they impressed Colonel Bonsal in the early part of 1920 are full of significance in regard to the probable position of Europe in the months immediately ahead.

The speech of Earl Winterton in opening the debate in the House of Commons shows clearly, however, that scientific workers have a special responsibility in this field to enable effective action to be taken. It is not disputed that the economic condition of the Western countries in Europe which have been subjected to the German occupation is serious. Nor can it be disputed that the position means much present human suffering and future political danger. It is clear also that a great responsibility rests upon Great Britain and the United States in the matter, since we command practically all external air and sea transport and, for military reasons, most of the internal transport. The figures quoted by Lord Winterton were not disputed by the Lord President of the Council in his reply, though Mr. Attlee insisted that there has been no discrimination against France, as Lord Winterton implied, and that France has shared in the general pool of shipping. Broadly, we are trying to get supplies from where they are to where they are needed, and at the same time to ensure the greatest economy in shipping, haulage and port facilities.

Mr Attlee's sober statement was somewhat reassuring, and in particular his announcement that the Ministry of Food was releasing to the liberated areas, which includes some of the Mediterranean areas as well, 900,000 tons of food from British stocks, and that the Ministers of Production and Food had gone to the United States at the invitation of the President to discuss the special food problems of the liberated areas. Mr Attlee's speech, furthermore, put the proposals with regard to 'food parcels' in their proper context, and his emphasis on the position of Britain as a food-importing country was phrased so as to avoid alike any possibility of international misunderstanding or recrimination, or doubt

as to the Government's realization that it is vital to get as good conditions as we possibly can in the liberated areas, as soon as we can. That, he agreed, is as essential for winning the victory of freedom and democracy as destroying the enemy in the field.

Mr. Attlee's statement should also help to make the position of the United Nations Relief and Rehabilitation Administration in this matter clearer, in this he was supported by Sir Arthur Salter, who pointed out that the activities of the Administration have always been subject to military considerations. Lord Winterton's fourth contention, however, was that the question for decision was whether we and the United States had taken sufficient remedial measures, having regard not merely to the supreme military needs of the moment but also to the fact that hungry people are not discriminating, and that France, Belgium and Holland are democratic countries *par excellence*. If the ordinary people there think that Britain and the United States have mishandled the food situation for military reasons, the war of liberation will cease to be as popular as it should and the liberating powers will not receive the gratitude they deserve.

This point was really met by Sir Edward Grigg in winding up the debate, when he said that in considering measures of military relief, the agreed policy of the United Nations is, and must be, to encourage the liberated peoples to assume responsibility for their own affairs as soon as possible. That is a definite instruction to all civil affairs officers who go into liberated territories. This assurance is welcome, as any other policy would involve the responsibility for future misery in Europe being saddled on Britain instead of firmly and primarily on Germany and the Axis Powers, and secondly on the local authorities responsible for local shortcomings.

Sir Edward Grigg's speech, while claiming that the military authorities, within their limited functions in the matter, have done and will continue to do their utmost to prevent disease and unrest in the immediate wake of the armies, never concealed that we are faced with a problem the gravity of which it is impossible to over-estimate, and neither his speech nor the trend of the debate as a whole left any room for complacency. A sense of urgency permeated the debate, and the suggestion advanced by Sir Arthur Salter that we should establish without delay an authority such as a supreme reconstruction council, comparable with the Supreme Economic Council established in 1919, was welcomed by one speaker after another before Sir Edward Grigg promised that the Government would take note of the matter.

Sir Arthur Salter's suggestion was for an authority which would co-ordinate for the principal victorious powers all their policy and efforts in assisting the reconstruction of Europe. He does not regard it as work for the Social and Economic Council of the Dumbarton Oaks proposals, or any organization set up as a result of the San Francisco Conference. He believes it is essentially a part of the peace settlement itself and should be established quickly, if

we thus supplement our present system, we have good hope of meeting the greatest challenge the constructive effort of men that has been witnessed in the history of the world, without it our present system will be completely inadequate.

There was, in fact, not only a large measure of agreement on this proposal running through the debate, but also on other aspects of the situation, the debate should have done something to educate public opinion still further as to the urgency of the situation, and to bring people to realize how serious is the problem and how grave is the prospect for European civilization if we do not take the necessary action now. The enlightenment of public opinion is an indispensable condition of success, in Great Britain as in other countries, for only so can we be sure that adequate support will be forthcoming for measures demanded, and that the personal sacrifices involved in the continuance of rationing and other necessary controls will be cheerfully accepted. At all, it is only the force of public opinion which can deal effectively with 'black marketing' and other disorders which endanger morale. Mere organization, however superlative, will never win the peace or establish a world order out of the chaos into which it is now clear that the Nazis have been deliberately seeking to engulf the whole of Europe.

In that task of education, however, scientists and workers have a special part to play, parallel to that which they played in regard to nutrition in Great Britain, and which, as Lord Woolton has justly said, did so much to secure the acceptance of a food policy which averted disaster. Dr. Haden Guest rightly pointed out that the United Nations Relief and Rehabilitation Administration has in fact done a great deal of valuable work in surveying the resources of food and materials and, if used as the Civil Service of a supreme economic authority, could do more still. The chairman of the combined food organizations has said that with the co-operation of Governments, the overall needs of Europe might be supplied, not indeed by moving rapidly to a full diet, but by providing a normal caloric grammage of rations. Certain items such as meat and fats admittedly are likely to be scarce for five or ten years or more, and Mr. Attlee referred to the danger of world shortages in fats and milk products particularly.

What is required, however, is to translate these terms understood by everyone, the meaning of the differences between the accepted standards of an adequate diet based on scientific investigation, such as the agreed minimum daily ration of 2,800 calories and those actually received in France, Italy, Holland or elsewhere, and the cumulative effect of the periods of starvation or semi-starvation deliberately imposed for four or even five years by Germany on the people of occupied Europe. The physical, mental and psychological consequences—the lowering not merely of physical vitality but also of powers of moderation and judgment through loss of vitamins and malnutrition—are matters of scientific fact which men of science are well qualified to interpret to their fellow citizens.

and it is one of their first duties to show convincingly why and how this policy of relief and food and medical supplies is both a humanitarian issue and a matter of the fundamental interests of the United States and Britain. They of all men and women should not need the words of Lord Templewood to remind them that unless we make a swift and united effort, the Nazis, although broken in the military field, may win in the civil by the victory of destruction. It is not, however, the question of food supplies alone, though that is important. As Dr. Eaden Guest and Mr. Greenwood reminded us, we have escaped epidemics so far, but the circumstances in which epidemics grow are being spread all over Europe at the present time. Prevention is very urgent indeed, and the displaced populations to which reference was freely made in the debate, whether refugees, prisoners of war or those forcibly deported, only accentuate the difficulties and dangers even in Great Britain we do not stand outside the range of large-scale epidemics if they start in Europe.

On this count also, Dr. Guest believes that some further inter-government staff organization is required. Besides this, however, there is the question of getting European agriculture and husbandry started again, as was emphasized by Mr. Greenwood and Sir James Gigg. Food and clothing are not the only necessities. Fertilizers, seeds and agricultural implements will also be required, apart altogether from the question of raw materials to get the factories in Europe started again, though industrial reconstruction is part also of this question of quickening European life. Even from the point of view of food supply, the reconstruction of European agriculture is an urgent task, the successful performance of which implies all the difference between peace and the return of individuals and nations to peaceful life. How important is this task and how great are the difficulties are well shown in an article

Prof. K. Brandt of the Food Research Institute, Stanford University, California, in a recent number of *Foreign Affairs*, which states that while such reconstruction must be the responsibility of national governments, economic policy should be worked out in international agreement. The major part of the work, however, lies outside agriculture, and Prof. Brandt points out that the recovery of European agriculture depends on the prior recovery of industry in Great Britain and all the Continental countries, and on the volume of post-war international trade, and primarily on decisions taken by the United States, the world's leading industrial power and the greatest creditor among the nations.

Prof. Brandt's article deserves attention, for the urgent problem of relief cannot be separated entirely from the long-term problem of reconstruction. The question was not always made clear in the House of Commons debate, except perhaps in so far as the fact that Great Britain is herself a food-importing country was rightly stressed. It is essential that the limitations should be as clearly understood as the implications of the continuance of undernourishment and starvation in Europe. It may well be

that such a gesture as food parcels may be administratively impracticable or inefficient. It may even be that on the examination which Sir James Gigg promised, Mr. A. P. Herbert's proposal for the assembly and organization of small craft to take food and supplies to the Continent as they once brought back the British army may prove impracticable, though for psychological reasons neither gesture of sympathy, apart from its practical service, should be lightly dismissed. If such proposals are rejected, however, the reasons must be clearly and fully explained, for the widespread public concern to which the debate testified cannot be disregarded. Moreover, if it is important that scientific workers should continue their task of interpreting the findings of the science of nutrition in terms of an adequate diet and a reasonable food policy not only for Britain but also for other countries, and that their attention to agricultural research should be sustained by a high sense of social service, it is equally important that the full facts of the world situation should be fully understood by the general public.

The people of Britain must be brought to recognize the limitations as well as the possibilities of action by their Government alone or in co-operation with those of other countries. The same generous spirit which inspired the idea of food parcels will effectively support the Government in whatever action may be required, and accept with patience and fortitude not merely the continuance of our present ration-scales which, as Sir Edmund Gigg said, are not large, but also, now that the fighting itself has come to an end, whatever further controls may be required to implement the chosen policy. To avoid reaction against such controls and rationing, and the all-important effort of food production on allotments, for example, their purpose must be made plain to all. Their relation must be demonstrated to the larger tasks of defeating the deliberate attempt which Germany has made to render civilization and an ordered life impossible in Europe, and establishing a world order from which disease and want and squalor have been banished, so far as lies within man's power.

SIX DECADES OF AMERICAN BOTANY

John Merle Coulter

Missionary in Science. By Andrew Denny Rodgers, III. Pp. x+321+2 plates. (Princeton, N.J.: Princeton University Press, London: Oxford University Press, 1944.) 25s. net.

THE history of botanical science in the United States is being duly surveyed and conserved. Already from the Princeton University Press there has come an account of the work of John Torrey, a volume on American botany from 1873 until 1892 is promised in the near future, now there is available a considerable work on John Merle Coulter. The method of presentation is biographical, but the work is really as much the history of a period as an account of the life and work of an individual. It is well that such studies should be undertaken before the essential

documentary materials are lost or begin the inevitable drift into obscurity

John Merle Coulter (1851-1928), who was to become a leading figure in American botany, graduated from Hanover College, Indiana, in 1870 and almost immediately began the active life of teaching and research that was to extend well into the present century. It may be profitable to pause for a moment and consider broadly some of the more evident antecedent and contemporary developments in biology, and of botany in particular, in Europe. Hofmeister's "Higher Cryptogamia" and "Allgemeine Morphologie" and the studies of Naegeli, Von Mohl and their contemporaries were available to botanists interested in the life-history, anatomy and morphology of many classes of plants. Darwin's "Origin of Species" had been published, Huxley's incisive views on the relation of the new scientific developments to contemporary theological views were already well known, while Hooker had shown what could be made of the systematic and geographical study of the flora of regions hitherto untouched. The great and progressive German schools of botany were in the ascendant and yearly were attracting more and more of the younger British botanists who had failed to find the guidance and inspiration they had sought in their own universities.

And now to return to the American scene. The education given at Hanover College—a Presbyterian foundation—was essentially classical, and not until 1874 was the teaching of science nominally put on an equal footing. Coulter's introduction to botany was through the medium of excursions. It is perhaps scarcely surprising that his initial interest, which he retained throughout his life, was in taxonomy. On all sides, in a vast territory where the recent decline in Indian warfare was making scientific expeditions possible, there was immediate work to be done in collecting, naming and classifying plants and in relating them to their highly diverse environments. Thus in 1872 we find young Coulter and other members of the Yellowstone Geological Expedition for-gathering in the Mormon town of Ogden. We are given a vivid picture of how their eyes opened wide as they walked through the town reading the signs above the Mormon stores "Holiness to the Lord," "Zion's Cooperative Mercantile Institution." Coulter set out on the expedition to assist in the geological survey, but, because of his spontaneous interest in plants and his zeal for collecting them, he returned with the official title of botanist. Thereafter, by steps that need not be described in detail, he became professor of natural science at Hanover, then at Wabash College, Indiana.

His essential contributions to botany in this initial phase were two-fold: first, like many of his contemporaries, he contributed to the production of regional floras, for example, his "Catalogue of Indiana Plants" (1881) produced in collaboration with his brother and Barnes, and secondly, he founded the *Botanical Gazette* in 1875. At that time he was probably a typical product of the prevailing Presbyterian background and, as the author informs us, to him "Science was the instrument of theology." Although a professed biologist, the theory of evolution was apparently not one which had stirred him deeply. But in 1879 and 1880, a new phase began. By attending the summer courses given at Harvard University under Prof. Asa Gray, the leading figure in American botany, and by coming into contact with such men as Farlow and Goodale, both of whom

had studied in the great European laboratories, he began to realize something of the potential scope of his science. The new studies included morphology, anatomy and physiology. It was made clear to him that observation, the basic method of science, must be amplified by experimentation. At that time probably not more than half a dozen botanical laboratories in the United States had other than taxonomic facilities for study, a situation very like that obtain in British universities. The publication of Bessey's "Botany" (1880), containing sections on anatomy and physiology, was a landmark. It apparently opened for American botany what the publication of Sauer's "Lehrbuch" in English (1775) did for British botany. At this point there occurs one of the most fascinating sketches in the book. It was probably typical of the beginnings of many New World institutions: concerns the young botanist Bessey, who, three months after graduation at Michigan, found himself called to the chair of botany and horticulture at the new Agricultural College of Iowa. He found "A few slender sticks" for trees, one building for the College, an old farm house, and two homes for Professors, in an open field, parts of which were later ploughed up to grow potatoes and corn. Inside the building there was no apparatus of any kind—not even a microscope. His first class of forty-three students was chiefly occupied with descriptive and systematic studies—for which purpose the class simply moved out on to the campus. In the winter of 1870-71 a compound microscope was purchased. This was placed on a table with some simple reagents and each student was allotted a period for microscopic study. On the door of the room was nailed a sheet of cardboard bearing the legend "Botanical Laboratory." No doubt the other professors jeered, but botany had come to stay.

Space does not permit of a citation of the gradual advance, diversification and deepening of American botany under such leaders as Gray, Farlow, Goodale, Bessey, Arthur and Coulter, or of the books which mark the successive stages. In many respects the remarkable parallel is afforded with comparable developments in teaching and research in British universities. Coulter himself stood for a science of the widest possibilities, and as editor of a journal of increasing influence was able to give his views a wide publicity. Indeed, his facility with the pen aided the spoken word, and his keenness as a promoter and supporter of new movements, may not be his least title to pre-eminence.

From 1880 onwards Coulter's output of work was surprising both for its amount and the diversity of interest which it disclosed. Thus there were studies of floral development, of the stamen, the embryo and the ovule, and of what may be described in general terms as physiological anatomy. By the year 1885 we may suppose that the teaching of botany in the United States was beginning to be more or less on an even footing with that in Europe, the work of De Bary, Strasburger, Sachs, Prantl and Vines being then in general use in American laboratories. The microtome was coming into general use and detailed studies of difficult materials correspondingly intensified. Cytology, gymnosperms and fossil material began to receive increasing attention. Coulter was associated with many of these developments, both directly and through his editorial activities, but his overriding interest was still taxonomic. In the survey of the vast territory of the United States there was still much ground to cover. Associated with

work the studies of plant geography and ecology developed apace

Coulter became president of Indiana University, then of Lake Forest College and finally in 1896 was elected to the chair of botany in the University of Chicago. The great days of American botany had arrived. A huge endowment, a matter of a million dollars, made possible the creation of the Hull Botanical Laboratory. Here Coulter's administrative experience stood him in good stead, and he soon had organized a representative department and had recruited to his staff young men with particular aptitude for the several special branches. Of such, for example, was Chamberlain, whose skill as a technician did much to advance anatomical and morphological investigations.

At the turn of the century Coulter, in the midst of any other activities, was still deeply involved in economic work. Thus, in collaboration with Rose, published, in 1900, "A Synopsis of Mexican and Central American Umbelliferae" and a "Monograph of North American Umbelliferae". At this time he was also gathering laurels as a morphologist and, together with D. H. Campbell, was elected to the American Academy of Arts and Sciences in 1898. The early years of this century saw the publication, in collaboration with Chamberlain, of the books by which he is probably best known to botanical students.

Great Britain, namely, those attractive books on "Morphology of Spermatophytes Gymnosperms" and "Morphology of Angiosperms". Together with his other papers and essays (on such themes as evolution, religion and science, etc.), his output of work was formidable. Coulter was, as his biographer remarks, "a prodigious worker and a lover of writing"—and it might be added of lecturing and public speaking. Indeed, it is not too much to say that he took a share, and a productive share, in all that was going on, and hence his work serves as an indication of the general trend of American botany. The developments in botanical science during the first three decades of the century cover more familiar ground and need not be considered in detail here.

There can be no doubt as to the interest and value of the work which Mr. Rodgers has undertaken and ought to fruition. On occasion, perhaps, one may entertain doubts regarding his sense of values—as, for example, when at various points he extols Coulter as a man of vision and prophet of the future of botany but this may well be true if restricted to its American context. Again, the American reaction to the controversy between science and religion during the Darwinian and post-Darwinian period, though, one feels, have been given more incisive treatment. There is also a question of the final evaluation of Coulter's contribution to science. Probably it is not soon to come to any decision. It may be that in reading himself over so many aspects of his subject and he left few untouched—he failed to make that major contribution which comes from concentration of effort and singleness of purpose, in other words, that he lost in depth what he gained in breadth. It may also be that the best use of his talent was not one to which he actually put it, that is, for the general advancement of a new science in a new country.

Lastly, in these days of books produced "in conformity with authorised economy standards", it is a pleasure to handle a work so clearly printed and so handsomely bound.

C. W. WARDLAW

SCIENTIFIC METHOD AND SOCIAL PROBLEMS

Race Relations and the Schools

A Survey of the Colour Question in some aspects of English Education, with a number of Proposals and Suggestions. Foreword by Dr G. P. Gooch (League of Coloured Peoples, 19 Old Queen Street, S.W.1.)

Social Differences in English Education

By T. H. Pear (From the *British Journal of Educational Psychology*, 14, Part 3) 7s. 6d.

IN his highly appreciative foreword to "Race Relations and the Schools", Dr G. P. Gooch lays it down that "conduct as a rule is determined by tradition and sentiment, and it can only be changed by greater knowledge, wider imagination and deeper insight". He reminds us that "their traditional values and way of life are as real and precious to coloured peoples as are ours to us, and that we can be proud of our own civilization without exhibiting a complacent and justly resented superiority complex".

Convinced that the race problem in the British Empire needed careful reconsideration, a group of English representatives of education, whose names and positions command the utmost respect, resolved to undertake a survey of the relevant contents of text-books of geography and history commonly used in British schools, both elementary and secondary. The results were certainly revealing, and constitute little less than a broad black blot upon the educational schemes of such a nation as ours. The investigation revealed, in fact, that in our school text-books, the life and needs of the sixty-five million coloured peoples of the British Empire, excluding India, are almost entirely ignored. This will never do. The days of exploitation are happily a thing of the past, and the days of benevolent trusteeship are at hand. The critical eyes of other nations are turned upon a nation which in the course of history has succeeded in painting a large part of the map of the earth's surface red, and criticism must be met with a clear conscience. This comprehensive report, which includes an examination of school-books, suggested methods of dealing with the colour question, and a useful bibliography, points the way to desirable changes, not extensive but nevertheless significant, in school-books, in training courses for teachers, and in films designed for educational purposes. The report is informed throughout with the spirit of scientific method.

Still more obviously—and one may even say unrelentingly—does the spirit of scientific method pervade Prof. Pear's paper on "Social Differences in English Education". He points out that English social stratification occasionally interests historians and economists, but that a psychological approach to the subject is rare. Psychologists are "blameless for the innocence of psychology displayed by the framers of the Norwood Report, and of the White Paper on education". He quotes a writer in the *New Yorker* who says that "from the rash and impetuous American viewpoint the English educational system, to our innocent eyes, has always seemed caste-ridden and money-dominated". Yet, adds Prof. Pear, there has been a taboo upon considering psychologically (that is, scientifically) these aspects of the system. In breaking this taboo he is well

aware that he may be asked what are his qualifications for the necessary degree of scientific impartiality and aloofness, seeing that a man can no more get away from his own upbringing than he can get away from his own shadow. To meet this objection, he gives enough of his personal history to enable the reader to judge for himself.

At an early point in his inquiry, Prof. Pear states a curious fact which has probably escaped the attention of many serious students of psychology. No living English professional psychologist appears to have come from any of the great public schools, no matter how strictly or loosely you define 'great'. We have no account of his social psychology, "written by one who not only sympathises with but 'empathises' their special culture pattern". We lack also a corresponding description of his way of living by a proletarian psychologist. Until recently, "our English social psychology has been written by the middle class about the middle class". He says this fact is well known, it is no doubt well known to some people.

Prof. Pear concludes his fresh and interesting investigation by expressing his full agreement with Prof. D. W. Brogan's opinion, that "politically England is a democracy, perhaps the most mature democracy in the world. But democracy is not merely a matter of government—it is an attitude to life. And England will not be a full or anything like a full democracy as long as one of the kindest and most united peoples in the world is internally divided in a fashion that impoverishes the national life".

Such is the verdict of one who has done his utmost to pursue scientific truth, wherever it may lead him.

T. RAYMONT.

NATURALISTIC PHILOSOPHY

(1) Verifiability of Value

By Ray Lepley (Columbia Studies in Philosophy, No. 7). Pp. xi+267. (New York: Columbia University Press, London: Oxford University Press, 1944.) 22s. net.

(2) Naturalism and the Human Spirit

Edited by Yervant H. Krikorian (Columbia Studies in Philosophy, No. 8). Pp. x+397. (New York: Columbia University Press, London: Oxford University Press, 1944.) 30s. net.

THESE two books are expositions of the naturalistic philosophy now popular in the United States and mainly derived from the teaching of John Dewey. The starting point is the view that scientific methods of investigation are valid for all spheres of thought and action. These Naturalists, however, do not use the arbitrary restrictive criteria of truth and verifiability of the Logical Positivists, and therefore their theory does not run counter to actual scientific practice as Positivism does. So far as the argument in Lepley's book is designed to show that judgments of value can be accommodated within the scientific scheme just as easily as judgments of fact and that they do constantly occur, it is evidently sound. Those essays in Krikorian's book which are straightforward inquiries into specific subjects are well done. Thus, Eliseo Vivas on "A Natural History of the Aesthetic Transaction", George Boas on "The History of Philosophy", Edward W. Strong on "The Materials of Historical Knowledge", the editor on "A Naturalistic View of Mind" and, especially,

Ernest Nagel on "Logic Without Ontology" make valuable contributions to their subjects—so far as they go. These essays display the best aspect of Dewey's teaching; they are careful, fair-minded, undogmatic.

It is when they come to questions which are more genuinely philosophical, those concerned with underlying presuppositions, that writers of this school tend to shirk or fumble. Lepley, in the first volume, argues that judgments of fact and of value, descriptive and normative judgments, occur together inseparably connected and that both sorts are found equally within the sphere of science, as ordinarily understood, and the spheres of art and morals; that verification in science, though perhaps simpler and easier, is not radically different from verification in art or morals. All this may be granted. But he fails to observe that discussion on matters of art and morals constantly turns on questions of ends, distinct from questions of means where the factual and causal element enters. In scientific discussion ends are taken for granted and are not discussed, so that all ordinary judgments that are in any way valuational or normative are judgments of means only. Lepley does not consider whether a judgment about an end, say truth or justice, can be dealt with naturalistically. Whether science can produce criteria to judge the value of its own method.

Similar defects appear in those essays in the second volume which should deal with such problems. In the one on "Naturalism and Democracy" by Sidney Hook, we are given to understand that the justification of democracy is that it is an experiment designed to realize certain moral ideals which is in fact successful, also that the moral ideals are hypotheses requiring empirical verification. Thus, if Hitler had won the War, the writer would presumably have decided that the democratic experiment had failed and the related hypotheses were false. Both Hook and Sterling P. Lamprecht, who writes on "Naturalism and Religion", consider that there is not enough empirical evidence to justify the hypothesis of theism, but the evidence is not examined, nor is there any attempt to discover those ends of thought and action of which religion is the expression. The writers appear to be following fashionable opinion instead of examining their presuppositions. Similar criticisms apply to other essays. This does not mean that their presuppositions are not in fact sensible or that their positive statements also sensible. It only means that they have neglected their philosophical duties. Nothing is said to prevent Naturalism from sinking to intellectual indolence. Science is fashionable, so let us call our opinions on any subject scientific and then stop thinking.

The essay on the Naturalism of Frederick Woodbridge by Harry Todd Costello (containing a pleasant story about Bernard Shaw) is puzzling, as are the other references to Woodbridge, because no writer in recent years has so neatly and effectively displayed the defects of Naturalism ("An Essay on Nature", 1940, p. 265ff). Three other essays should be mentioned. One, on "The Unnatural", a good piece of metaphysical argument, seems rather out of place among its companions. One, on "Naturalism and the Sociological Analysis of Knowledge", may be excellent but is written in a difficult dialectical jargonese. Finally, there is an essay by the octogenarian Dewey, who attacks the things he dislikes with a vigour that puts more youthful disciples to shame.

A. D. RITCHIE

CO-OPERATION IN THE WAR AGAINST DISEASE

By SIR PHILIP MANSON-BAHR, C.M.G.

THE modern statesman is inclined to reject the terms of narrow nationalism, both in commerce and policy. He maintains his faith in the development, for the public good, of such co-operation and good-will which cannot be compatible with international mistrust and concealment. He is impelled to adopt this view, it is hoped, by the ideals of humanitarianism no less than by logic which implies search for efficiency. Yet it is self-evident that at present, without a radical change in method of government, which would go beyond political imagination, the control of geographical areas, or countries, must rest with the people of those areas. How far this control should be sovereign is a matter for debate, but there is little doubt that, in the matter of transmissible disease, the safety of the whole world community ought to take precedence over the rights of any particular people. In this respect there is one subject into which political considerations do not intrude and that is the advisability of a united, co-ordinated policy in the war against disease. This stands for the communal good. It is therefore opportune to formulate some ideas how such a campaign may be conducted. The causes of the main tropical and subtropical diseases are now well known, their conveyance to man and their effective treatments accurately ascertained. A proviso should here be made that the diseases, so named, may also be important in temperate lands. To illustrate this point, reference may be made to certain of these diseases and to some of the reasons which compel international attention. In this article, certain problems will be briefly stated and certain lines indicated which appear indispensable to their solution.

Malaria is perhaps the commonest disease in the world, it takes a heavy toll of infant life and causes more incapacity than most people realize. But it is not a static disease, it may, from time to time, appear in epidemic form and as such spread over international boundaries. To understand this it is necessary to comprehend something of the modes of spread of this disease, which is a complex partnership between the parasite, the mosquito, and man.

The cause of malaria is, of course, the malaria parasite, of which four species are recognized in man, they differ from each other in appearance and in their effects. The most dangerous is undoubtedly the malignant tertian parasite, which is particularly tropical in its distribution—though found as far north as Italy, Greece and Rumania—and which is the essential cause of the much-dreaded blackwater fever, a sequel which has cost the lives of so many Europeans in Africa and elsewhere.

The limited range of this parasite is explained by the ascertained fact that it requires a higher atmospheric mean temperature to complete its development inside the mosquito. It is one of those unexplained, and at present almost inexplicable, facts of biology that only mosquitoes of the genus *Anopheles* have been proved capable of transmitting malaria from man to man. In members of this genus the malaria parasite undergoes an essential stage of development before it is capable of once more

infecting man, but for the essential points in the present argument it is necessary to realize that not every member of the genus *Anopheles* is able to transmit malaria, that of those species which can do so, some are highly effective and others less so, that their effectiveness depends largely on the degree to which a species seeks human blood rather than that of animals, and that the effective spread of malaria depends upon the ability of efficient carrier mosquitoes to herd in close association with man.

Of efficient carriers there are at least six in Africa and many more in Asia. For breeding, some species need water open to the sun, others demand shade, some need relatively high temperatures, others prefer cool waters, some even require brackish water which is prohibitive to others, some need clear, limpid streams, others will breed in a muddy water-filled hoof-print. Then different species of *Anopheles* have characters which are relatively constant and are therefore vitally important. Thus a locality may be infested with *Anopheles* and yet have no malaria, but a change in agricultural habits of the people, for example, introduction of artificial irrigation, may so modify the composition or condition of the water that *Anopheles* of dangerous species, present in contiguous areas, may infiltrate, to initiate an epidemic of malaria in a population devoid of immunity.

In other circumstances the water may be suitable to the breeding of *Anopheles*, but these mosquitoes may not be present. If in such cases they are introduced, and, if persons carrying the malaria parasite in their blood exist in sufficient numbers, then conditions for epidemic transmission will have been created. This is the present position in certain groups of islands in the Pacific. *Anopheles* are not yet there, but may well be introduced in ships or in aircraft from other lands.

Again, malaria may be present, but the local *Anopheles* may be a relatively poor transmitter, so that the disease is maintained at a low rate of incidence, but if to such a community a vigorously breeding, man-loving *Anopheles* is introduced, the result may be an epidemic of malaria lasting many years, in which the human death-roll may amount to tens of thousands. This is not speculation, but is exactly what happened to Brazil about 1930, when that most versatile malaria-carrier, *Anopheles gambiae*, was transported from West Africa to Brazil in the fast steamers which ran between Dakar and Natal (a port in Brazil), became established there and carried death and ruin to a large peasant population for ten years. At the cost of enormous exertion, this mosquito has at last been eradicated from Brazil by the combined efforts of the Government and the Rockefeller Foundation, and the epidemic has ceased, but though the organization which made this great feat possible was brilliantly conceived and should serve as a model for the world, the tragic episode underlines the overwhelming truth of the old adage that prevention is better than cure, and prevention would be difficult without co-operation between sovereign States—between the country from which the mosquito originated and that to which it travelled. Prevention demands, for example, that no mosquito which may enter an aircraft at an aerodrome in West Africa should be allowed to escape on arrival in Brazil—the authorities at each end must take their complex precautions. Moreover, the work of eradication of *Anopheles gambiae* from Brazil was assisted

by—note the title—the International Health Division of the Rockefeller Foundation. India also has its own malaria problems, but India knows no *Anopheles* so vicious as *Anopheles gambiae*, and it is conceivable that this mosquito, to which West Africa owes most of its evil health reputation, might be taken by aircraft to India, there to repeat its Brazilian feat. Thus the rapidity of modern travel has raised problems previously unknown.

It is therefore clear that prevention of malaria on an international scale entails the close co-operation of specialists in many directions. It demands the mutual understanding between doctors, entomologists, agriculturists and irrigation engineers, without this an individual alone is helpless. The medical entomologist is there to identify the *Anopheles*, to detect its breeding places and to direct methods for its eradication. To give some idea of the technicalities involved it has to be pointed out that there are variations even in one species which are of great importance. Thus *Anopheles maculipennis*, the chief transmitter in Europe and North Africa, is divisible into no less than seven races in the Old World and one in the New, which can be distinguished from one another (like birds) by the colour pattern of their eggs. Some are important species in the present sense, others not at all.

What is true of malaria bears a definite relation to another great mosquito-borne disease—yellow fever “Yellow Jack” once destroyed one of Napoleon’s armies in the West Indies and frustrated the French attempts to force a canal through Panama until finally defeated by the Americans under General Gorgas, it was the terror of Caribbean sailors and West African traders, the pernicious and deadly jaundice which gives it its name was the origin of the yellow colour long ago adopted, and still maintained, for the quarantine flag. Yellow fever is caused by an ultra-microscopic virus, a group of organisms the members of which include the causes of measles, influenza, smallpox and numerous plant diseases, and this virus is transmitted from the blood of infected man to that of a healthy individual by mosquitoes during the act of biting. Unlike human malaria, yellow fever is a disease which affects certain wild animals, particularly South American monkeys, opossums, which constitute a reservoir of disease that must be taken into account, and it is transmitted chiefly by mosquitoes of the genus *Aedes*, of which the most important is the semi-domestic species—the tiger mosquito—*Aedes aegypti*.

These mosquitoes are abundant throughout the tropics, in America, Africa and Asia, but yellow fever has fortunately not hitherto been known in Asia and Australia. Should the virus be introduced there, the stage would indeed be set for an epidemic the like of which has, perhaps, not yet been known, and although there is a vaccine which, when inoculated, affords excellent protection, inoculation of the millions of people in India and the Far East would be such a gigantic task that it is preferable to take the most extensive and radical measures to prevent the entry of this disease.

But an infected mosquito might enter an aeroplane in Africa and escape from it in India, might infect a villager who in turn might infect a dozen local *Aedes*, and so on. Or, again, a man in Africa might travel by air to India during the incubation period of the disease before recognizable symptoms develop, on arrival the disease might not be readily diagnosed, and in the interval he might easily infect local Indian

Aedes aegypti. All this is, of course, well recognized, and active precautions are being taken to guard against such happenings, but it is by no means easy to realize how detailed and how fine must be the system which attempts (so far with success) to protect the East against yellow fever. One crucial point in this protective system is international co-operation. Each threatened country must take its own precautions, but each already infected country has a responsibility to ensure that aeroplanes departing from its aerodromes do not carry with them infective material, human or otherwise. International conventions have indicated how these responsibilities should be met.

African trypanosomiasis (sleeping sickness) has for centuries played havoc with the natives of that disease-ridden continent, but as yet this affliction is confined to Africa. It is caused by a tiny protozoan in the blood, which is picked out and transmitted in the act of biting, by tsetse flies. It is, again, one of the unexplained mysteries of biology why this organism is so selective that it cannot be transmitted by mosquitoes (apart from occasional mechanical transmission by certain other biting flies), and that it cannot undergo its essential development in insects other than the tsetse, yet the fact remains.

In the days of slave trading, negroes suffering from sleeping sickness were often transported to the West Indies. They died there of the disease, yet sleeping sickness was never established in the western hemisphere, because the requisite flies did not exist there. The tsetse is a land fly, it does not frequent harbours, it has no incentive to get aboard ship, but it does seek shade, and may be attracted to the shade of an aeroplane standing near a patch of trees on an aerodrome, it may enter the aeroplane and travel with it, and if living infected flies were to reach parts of America and become established there, there is little doubt that the disease would be propagated. The danger is, perhaps, somewhat remote, but the discovery of dead tsetse flies in aircraft arriving in Brazil has been regarded as something of an omen by the South American authorities.

These three diseases illustrate the fact that in warm climates some of the major dangers to health are transmitted from man to man, or from animals to man, by flying insects. But there are great epidemic diseases, conveniently labelled tropical because their present incidence is mainly in hot countries which are, in fact, diseases of all climates and which are transmitted by arthropods which do not fly.

Plague was more than once rampant in England—the Black Death and the Great Plague were instances of spreading epidemics—and is now present in the rodents of the United States, as well as of Africa and Asia. It is essentially a disease of rats and field rodents, and is spread among them by their fleas. Fleas leave dead animals, and in default of living rodents on which to feed, will attack man. The cause of plague is a bacillus which is present in the blood of a diseased animal, and which is taken up by the flea when it feeds. In the flea it multiplies, and, in certain circumstances, may be injected into another animal (or man) at a subsequent feed. There is thus the cycle rat-flea-rat, and if the mortality among rats is high, and the chance of feeding on rats consequently low, and if the rat community is in close association with man, there is a spill-over of plague to man, which, in extreme conditions, may be

at proportions, with devastating epidemics. Rats, of course, seek food which is to be found especially in human habitation, or in food stores, in bazaars in the East, and in ships. They are great climbers, and a dock area heavily infested will, unless transit is prevented, both give to and receive from incoming ships considerable numbers of rats. An infected rat may invade a ship, start the disease in the ship's rats, and an infected rat may leave the ship at another port, infect the rats of that port, and originate an epidemic in man. This course of events has happened often in the past and the danger is always present. There has recently been an outbreak in Haifa and in Haifa, the rats of Rangoon and Hawaii have been infected for many years, human deaths from plague are constantly reported from Istanbul, in India, Java, and Madagascar plague in man is constantly present.

Plague, therefore, is a disease which is peculiarly associated with commerce and trade routes, with ships and shipping. These are pre-eminently the international links, and it is just here that control measures must be, and indeed are, co-ordinated by international agreements.

Typhus, which Zimsser regarded as a more potent factor of the fate of nations than the Caesars or poleons of history, is transmitted from man to man by the louse. It is caused by a minute organism which is taken in by the louse when it feeds. Typhus flourishes when lice flourish, in cold weather when the thing is not often removed, and particularly when civil life is disorganized by war, with its masses of refugees herded together and without the means of cleanliness, or in famine, when the people flock to the great cities and live in crowded conditions, as in North Africa. Typhus killed more people than all the weapons of war in 1914-20, in the present War the attention given to it by the Germans indicated its relevance they were not anxious to admit. In North Africa the incidence has been heavy during the last few years, in China the refugees from invasion were widely diseased, in Spain a violent epidemic followed the civil war. The introduction of typhus into a crowded community, which is already infected with the necessary lice, may produce the final condition needed for an outbreak.

Those diseases which are not specifically insect-borne present problems not less complex and not less urgent. Cholera may be introduced into a country by the movements of labourers, by pilgrims or by refugees from war, smallpox has many times invaded tropical countries in the same way, the common enemies of childhood, such as measles, at one time wreaked havoc in Fiji, where the natives had no immunity, and the same course of events has recently been enacted in remote villages traversed by the newly built Alaskan highway. The same thread runs through these happenings—the introduction into one area of diseases prevalent in another, across national boundaries.

Moreover, there are less spectacular diseases, such as tuberculosis, leprosy, venereal diseases, yaws, hookworm infection, unevenly spread over the tropics but affecting grossly the health and happiness of enormous communities, and their eradication could not satisfactorily be undertaken by the uncorrelated actions of individual States. These are the responsibilities of Governments, but the resources of some of the tropical countries are totally inadequate to their needs. At the root of much of this chronic illness is the poor state of nutrition of the people, the poor

state of agricultural knowledge and equipment and the low state of general hygiene.

The science of nutrition is still in its infancy. This sounds a queer statement, as the desire for food and the adequate nutrition of the body is surely a primitive instinct. So it comes as a rude awakening to realize that lack of proper ingredients in the diet is at the root of most human evils. Just as weeds will grow and flourish on poor soil, so will the germs of disease when the defence mechanisms of the human frame are weakened by insufficient nutriment.

It has now been established beyond doubt that the majority of tropical peoples are existing on grossly insufficient foods. This is especially the case in the West Indies, Central Africa and China. There the native foodstuffs do not provide the necessary amount of proteins and fats. Some tribes are undernourished because they do not eat meat or drink milk, even when they are at hand. There are taboos, traditions and beliefs—all so ingrained that it may take centuries of education to eradicate them. There can be no reasonable doubt also that wrong feeding is one of the principal causes of the very high infant mortality in most tropical countries.

The main facts are summarized in the two reports of the Economic Advisory Council on Nutrition in the Colonial Empire published in 1939. A study of this mass of information makes illuminating reading and strengthens the belief that the subject of nutrition is all-pervading and of the utmost importance. It is the ground rock of health and one which underlies the maintenance of virile and healthy populations. It strengthens the belief, if proof were needed, that if the soil of the body is defective, no medical skill or specific drug treatment can be effective in eliminating the seeds of disease.

The argument sustained by these facts is that the responsibility of the advanced countries to their own peoples demands that they should urge the less advanced to prevent the export of transmissible disease, as well as that they should themselves prevent its ingress. The less advanced must be persuaded to adopt those sanitary measures, those quarantine restrictions, that the community of nations considers necessary to general well-being. But the advanced have a human responsibility to the uneducated peasant populations of other lands, which should not be estimated on a safety basis or on a cash value. Self-interest is not a policy that can appeal much to a world which wants a faith, and in medicine more than in any other human activity there is need for co-operation and the pooling of resources on the widest scale.

To be more precise, the Government of each nation must do its utmost for the health of its own people, must protect its own people from disease brought in from abroad, must ensure, so far as possible, that reasonable steps are taken to prevent the export of its own diseases, and must be prepared to place at the disposal of the rest of the world reports on its own health and swift news of any major epidemic outbreak. The last, indeed, has already been the rule on a large scale, and before the War the Far Eastern Bureau of the League of Nations at Singapore issued early warning of the great tropical epidemic diseases throughout its area. The Pan-American Sanitary Bureau, and the Paris International Office of Public Hygiene performed like functions. But these organizations were not world-wide, they were not complete, and the position cannot be satisfactory until completeness is achieved.

Again to be precise, the controlling Governments of tropical Colonies must render to those Colonies services more regulated by their needs than by their capacity to pay. These services, in the matter of health, include education and research, equipment and personnel on a scale not often attempted, and embracing not only medicine but also agriculture, animal husbandry and industrial development. Moreover, it is a moral responsibility for the more advanced nations to lend to the less fortunate nations, without thought of reward, the services they need, even if those less fortunate peoples are self-governing.

Apart from good-will, high ideals and financial help, the essential basis for this co-operation between nations is knowledge. First, there is the knowledge of the outbreak of transmissible disease. This information must be given by the affected country to a central organization with the utmost speed and accuracy, so that spread to other countries may be prevented.

Second, there is the knowledge of the general state of health of these countries. Much of this can be, and in fact is, contained in official annual medical and health reports, but for many of the countries of the tropics such reports are difficult to obtain, or are not made. Any person interested in the health conditions of the British Crown Colonies, or of certain tropical dependencies of other nations, has at his disposal a satisfactory range of annual reports, but some other countries, of great importance to world health, do not offer this service.

Third, there is the knowledge of the complex problems of disease, which is being slowly and painfully acquired by research workers and investigation throughout the world. This knowledge is made available through the medical journals of all countries, which now make up a mass of literature so great, and in such a multiplicity of languages, that few workers even in restricted subjects, and none in wider fields, can hope to read all that should interest them. Outstanding achievements soon receive universal recognition, but each outstanding discovery is followed by a mass of investigation which modifies and re-assesses its application and value. It is necessary that accounts of this work be assembled by some agency in a form convenient for those who, desiring to know of it, are unable themselves to perform the tedious task of searching the literature.

Apart from the international aspect of this problem, the British Empire has a definite responsibility towards the many peoples over whose welfare it presides. Promotion of medical knowledge and raising the standard of health in every portion of the globe is the best method of securing good-will and strengthening the machinery of government. Medical education is being extended on British lines in India, Ceylon, Africa and elsewhere. The needs of native medical schools and practitioners has to be catered for by the dissemination of knowledge. It is therefore eminently desirable that Great Britain should take an honourable place in the provision of medical information suitable to its world-wide responsibilities. To strive for such an ideal is surely not beyond the powers of a nation which has stood shoulder-square to the perils of the last five years of war.

I wish to express my indebtedness to Dr. Charles Wilcocks of the Bureau of Hygiene and Tropical Diseases for his helpful advice and assistance in the compilation of this article.

AUTOSYNTHETIC MOLECULES

By DR. T. F. DIXON

KNOWLEDGE of the mechanism of cellular protein synthesis has been advancing rapidly with the aid of the ultra-violet and electron microscopes. Nucleic acids show characteristic light absorption maxima at 260 $m\mu$, due to the purine and pyrimidine constituents which distinguish them from other substances in biological material. By using a quartz microscope with monochromatic ultra-violet light, information has been obtained about the role of nucleic acid in cell division¹ and the nucleoprotein nature of the chromosome and gene^{2,3}. Indirect evidence for the latter has been obtained by ultra-violet irradiation of germinal tissue, when high efficiencies of mutation have been observed at 260 $m\mu$.⁴ Viruses also appear to be nucleoproteins.

All animal and plant cell nuclei give positive Feulgen reactions, indicating the presence of deoxy-pentose, whereas pentose is characteristic of the cytoplasm. Variations occur not only in the sugar and pyrimidine components of the nucleic acid portion and its degree of polymerization, but also in the proportion and nature of the protein with which the nucleic acid is combined. Thus nuclear material from fish sperm heads (the classic example) contains approximately 2 parts of nucleic acid combined with 1 part of the strongly basic protein protamine, whereas in tobacco mosaic virus nucleoprotein 6 parts of nucleic acid are linked with 94 parts of a less basic and more complex protein. The nucleoproteins may form complexes with lipids. For example, the viruses of Rous sarcoma⁵, equine encephalomyelitis⁶ and the elementary bodies of vaccinia⁷ have been shown to be associated with phospholipid-nucleoproteins.

The word virus has been applied mainly to agents residing in multicellular organisms, and when individual free-living cells are the hosts, such as bacteria, they are referred to as bacteriophages. The property of obligate parasitism or infectiousness has been found to be associated with certain high molecular weight nucleoproteins which are foreign to the host proteins and are probably the viruses themselves. In many cases one attack of virus disease in an animal may produce a lasting immunity demonstrable by certain serological phenomena such as complement fixation, agglutination, precipitation and neutralization. Enduring immunity may depend on the kind of tissue infected and probably due to a long-term sojourn or persistence throughout the life of the host. Lasting immunity may not be obtained to influenza or to the common cold virus because the superficial cells lining the respiratory tract are being thrown off at intervals and replaced by deeper cells, and thus do not provide a permanent abode for these viruses. The fact that injection of immune or convalescent serum has little influence on the course of some virus diseases is not surprising when it is considered that the viruses are multiplying within the cells and may never be subjected to the action of humoral antibodies.

Certain cancerous growths are associated with viruses. Such growths are transplantable, and agents with which the disease can be produced again can be extracted from them. Thus viruses are responsible for tumours of the renal epithelium of frogs, for

variety of mesodermal growths of fowls and for papillomas of rabbits. In some cases viruses may be the causal agents, and the chemical carcinogens the 'provoking agents'. The 'milk factor', the transmissible agent of mouse mammary cancer, may cause no growths until it is 'provoked' by an oestrogen. That anti-viral antibodies frequently attain great strength in the blood of virus-induced tumours without preventing their growth is probably due to the selective permeability of the cells, which will neither admit haemolysins or antibodies against bacteria nor those against viruses. The cell itself may be regarded as the host of the tumour virus, and not the organism which becomes implicated secondarily.

The nucleoprotein viruses of animals, plants and bacteria differ in size, stability and chemical composition. Their sizes⁸ range from the larger, more complex and organized viruses such as vaccinia with a diameter of 225 m μ and an estimated molecular weight of 4.3×10^9 , to the smaller viruses such as foot-and-mouth disease with a diameter of 10 m μ and a molecular weight of 4×10^6 , which perhaps may approach the minimum limit of size for self-reproducing particles. As an obligate parasite, vaccinia, or any other highly organized virus, may possess only a portion of the enzyme systems necessary for existence, relying chiefly on the intracellular nuclei for complementary systems enabling it to multiply. Although no independent metabolism of vaccinia has been demonstrated *in vitro*, it has been shown that copper, flavin-adenine-dinucleotide, biotin, phosphatase and catalase are present⁹. On the other hand, lipase, catalase and phosphatase were adsorbed from their solutions by the virus with ease and could not be readily eluted, so that it is difficult to distinguish between the enzymes which may represent an integral part of the virus and those which may be contamination from the host. In contrast to the simpler plant viruses, the more complex animal viruses such as vaccinia, psittacosis, yellow fever or lymphocytic choriomeningitis give rise to more than one specific antibody.

Electron micrographs of vaccinia indicate six rectangular plane surfaces and five dark areas¹⁰, showing in many ways resemblances to bacteria and marked differences from plant viruses. Tobacco mosaic virus particles appear as rods 280 m μ long and 15 m μ across, representing a molecular weight of about 4×10^7 . Bacteriophage suspensions consistently show the presence of sperm-shaped particles adhering to bacterial membranes¹¹. The particles consist of heads 80 m μ in diameter and thinner tails 130 m μ long, and in the presence of sensitive bacterial cells absorb by either head or tail. X-ray diffraction studies on tobacco mosaic virus¹² show that it is built up of hexagonal prism units 8.7 m μ tall and 7 m μ across, with a molecular weight of 3.7×10^6 . There are also transverse spacings and demarcations at 4.4, 2.2 and 1.1 m μ . It may be speculated that during self-reproduction, the assembling of these units of 1.1 m μ cubes, containing perhaps eighteen amino-acids, leads to the construction of a layer, and that the virus may consist in part of similar layers joined by nucleic acid fragments.

The production of a mild form of a disease to create an active protection has long been known generally, as with bacteria, it is not practicable to produce an artificial protection with small amounts of a fully virulent virus under conditions corresponding to natural infection, since there is the danger of provoking a severe attack in a susceptible

patient. Unlike bacteria, viruses cannot usually be treated with formaldehyde or other chemicals *in vitro* to destroy their virulence without losing their antigenic properties in a parallel manner, although they may lose their virulence or their tropism for a particular tissue by repeated transmission through another host. Long-known examples of modifications of viruses which can induce protection are the Jennerian cow-pox, probably arising as a mutation of human smallpox, and the modified Pasteur rabies virus produced by brain-to-brain passage in rabbits. A third more recent outstanding example is the yellow fever virus strain 17D which was evolved by hundreds of passages in tissue culture in media containing embryonic tissue from which neural tissue had been removed. The resulting virus lost its neurotropic character and has been widely used for human immunization¹³. Nothing was known concerning the chemical changes involved in the production of a given variant until amino-acid analyses were performed on six mutant strains of tobacco mosaic virus each producing characteristic leaf symptoms and which had been prepared in essentially pure form. Briefly, besides serological differences, tobacco mosaic, green and yellow aucuba, J14D1, Holmes masked and ribgrass strains showed differences in their contents of tyrosine, tryptophan, phenylalanine, arginine and sulphur. In addition, the ribgrass strain contained histidine, which was not detected in the others^{14,15}. Attempts to alter the tobacco mosaic virus *in vitro* have been made by preparing acetyl-, phenylureido-, carbobenzoxy-, *p*-chlorobenzoyl- and malonyl-derivatives¹⁶. Providing the reactions were not carried too far, a large portion of the amino- and phenolic-groups could be combined without loss of infectivity. Although the derivatives failed to perpetuate themselves as such and the virus eventually isolated was the ordinary tobacco mosaic virus, it is hoped eventually to obtain known structural changes in a virus which will be heritable.

Both virus and gene have the ability to reproduce within, and only within, certain living cells, and may undergo changes spontaneously or as a result of external factors. That new virus strains appear to become dominant when grown in an unnatural host suggests that the altered environment of the host may supply different building blocks. In general, a chemotherapeutic agent deprives an organism of essential enzymes or metabolites. It may do this, with bacteria, by interfering with capsule formation or by altering cell permeability so that essential metabolites are either washed out of the cell or fail to penetrate it. Or there may be competition with a structurally similar essential growth-factor at enzyme surfaces, as postulated for the sulphonamides and *p*-aminobenzoic acid. So far, the few viruses which have proved susceptible to sulphonamides, such as the agents of lymphogranuloma venereum, inclusion blennorrhoea and mouse pneumonitis, are those which in complexity and size occupy a position, perhaps analogous to the rickettsia, between bacteria and the smaller, less organized viruses, and their susceptibility may express their more complex needs and metabolism. Research into the metabolic requirements of the viruses offers an opportunity for a fundamental reasoned approach to their chemotherapy which has been lacking in the search for antibiotics. The susceptibility of organisms in general to virus infections when inadequately supplied with essential feeding-stuffs merits full investigation. In particular, bacterial viruses should serve

well for this study, since their growth can be observed quantitatively under controlled conditions

It has long been known that X- and γ -rays interfere with gene function and suppress organizer action, and that this is connected with the beneficial effects of radiotherapy in cancer. Recent work¹⁷ bearing on intracellular metabolism and the gene-cytoplasm equilibrium shows that these rays inactivate certain enzymes and viruses *in vitro*, and in proliferating and in incompletely differentiated cells produce an inhibition of desoxypentose nucleic acid synthesis in the nucleus and an accumulation of pentose nucleic acid in the cytoplasm.

Nucleoproteins are found in high concentrations wherever growth occurs in a living medium, whether in the metaphase chromosome, the normal gland cell, the avian neoplasm or the embryo. The cell was once considered the ultimate duplicating life-unit. Now the nucleus is thought to be the centre for protein synthesis, and the nucleic acids the essential units, either as polymerized desoxypentose nucleic acids associated with the gene proteins (of which chromosomins are stated to be a constituent¹⁸), or as cytoplasmic pentose nucleoproteins. Examination of the nuclei of rat liver cells has not revealed the complexity or concentration of the enzymes which are found so abundantly in tissues or organs¹⁹. This may be because the genes produce only formative enzymes of the sort used in protein synthesis. The use of radioactive nitrogen (¹⁵N) as a tracer has shown that nearly all body proteins even when fully synthesized are continually undergoing breakdown and repair and exist thus in a state of dynamic equilibrium, and this probably applies to the gene and cytoplasm proteins²⁰. When an oestrogen causes proliferation of uterine epithelium, when a carcinogen produces a sarcoma or when an evocator stimulates a gastrula to neural differentiation, certain circulating compounds may act on this gene-cytoplasm equilibrium in the particular tissue causing it to be reconstituted in a different way. Thus at a critical instant in the life of the tissue, a crucial cellular reaction may be influenced, causing differentiation to proceed towards one type of cell or another. Although knowledge of the intricate processes occurring in the cell is very far from complete, the pattern of organization and nuclear structure is just beginning to appear.

THE SUPER-FLUIDITY OF LIQUID HELIUM II

THE study of the properties of liquid helium has been very fruitful in revealing unexpected phenomena—super-conductivity, abnormally high thermal conductivity, super-fluidity and others. Of these, super-fluidity and some associated effects are comparatively new and were being investigated in several laboratories just before the War. Prof P Kapitza, who is one of the chief workers in this branch of low-temperature physics, and who introduced the term 'super-fluid', has recently published an article¹ in which he surveys his work on this subject and discusses possible explanations of the flow phenomena.

When helium is progressively cooled below 4.2° K (the liquefaction point) under atmospheric pressure a change takes place at 2.19° K, the λ -point. The most obvious effect is the sudden cessation of boiling. The change is usually referred to as the passage of helium I into helium II, and the peculiar properties of liquid helium are associated with helium II, for example, Keesom found that the thermal conductivity of helium II in a capillary was many times greater than that of the best metallic conductors.

Kapitza repeated Keesom's experiments under somewhat different conditions and obtained still higher figures for thermal conductivity. It was while seeking an explanation for this effect that he was led to the idea of super-fluidity and to the carrying out of experiments² which proved that the viscosity of helium II is vanishingly small. The normal mechanism of heat conduction—the handing on of thermal agitation from molecule to molecule—could not apply in this case, and the alternative appeared to be a form of conduction by means of convection currents; but, if this were the method, gravity was not a sufficient cause and convection currents must arise with extraordinary ease in helium II, implying that the liquid had an exceedingly small viscosity.

The latest determinations of viscosity have indicated a figure of 10⁻¹¹ poise as the provisional limit. This is a thousand-millionth that of water, and may be reduced still further if the sensitivity of the method can be increased.

Confirmation that powerful convection currents of a special type can occur in liquid helium II when a temperature difference is set up was obtained by Kapitza by means of the apparatus shown diagrammatically in Fig 1 (this and the other diagrams are from Prof Kapitza's paper, ref 1).

Fig 1

Fig 2

A small flask (1), open at the neck (3) and containing a heating spiral (2) was immersed in super-fluid liquid helium. When an electric current was passed through the spiral, a continuous current of helium was found to flow out through the neck of the flask. A delicate vane suspended in the neck was deflected by this current and served to measure its force and speed. An apparatus more suitable for demonstration purposes is illustrated in Fig 2. A cinematograph picture has been taken of this apparatus in action. A glass 'spider' mounted upon a needle (1) consists of a small bulb (2) provided with a number of outlet tubes which are all bent back in the same sense. When the whole spider was immersed in liquid helium II and the centre vessel heated by directing light on to the blackened interior by means of a lens, a continuous stream of liquid issued from each of the little tubes—the legs of the spider—although there was actually no through channel for liquid in the spider. As a result of the reaction of the escaping liquid, the spider was caused to rotate.

Reverting to Fig 1, the paradox of the experiment is that no return flow was ever detected with any position of the vane. The explanation first suggested for this was that the return flow might be in the form of a very thin mobile film along the glass surface. To test this theory, the wide mouth of the flask was replaced by a very fine slit to cause the whole slit opening to be used by the suggested reverse current following the wall. The width of the slit, which was made with great precision, was reduced by stages to 0.14 micron, but no change in the character of the phenomenon was observed.

Experiments with slits brought out the important fact that the effect is thermodynamically reversible. The thermally induced rotation of the spider (cf. Fig 2) in a liquid which, being super-fluid, causes no frictional loss, provides a mechanism which has the utmost possible coefficient of efficiency.

When helium II flows through a capillary from a higher level to a lower (Fig 3) the liquid at the lower level is found to be cooler than that at the higher. If this effect remains reversible however low the temperature, then by forcing liquid helium through capillaries and repeating the process a sufficient number of times we should have a method of getting as near as we might wish to absolute zero. Employing this method, Kapitza was able, just before the War, to obtain a reduction in temperature of 0.4° and he is now proposing to proceed with these experiments. The normal method of cooling, which depends upon the de-magnetization of para-magnetic salts, has both theoretical and practical limits to its further

usefulness, but there is no reason to suppose that the flow method has any limits whatever.

When the slit experiments appeared to dispose of the film theory, the flow phenomena (Figs 1 and 2) appeared utterly mysterious. A theory which appears at first sight to be incompatible with normal physical thought has been evolved to explain them. Its first rough outlines were sketched by Tisza in 1938³, but its scientific development is due to the Soviet physicist, L. Landau⁴. According to this theory, at temperatures below the λ -point liquid helium is a mixture of two liquids, one of which is a normal liquid and the other a liquid characterized thermodynamically by zero entropy and physically by the absence of viscosity. Just above 2.19° K the liquid is entirely in the normal state. As the temperature is lowered, super-fluid helium starts to appear, and its concentration increases progressively and that of ordinary helium decreases until at absolute zero the whole liquid, so it is supposed, has zero entropy and no viscosity. This picture is adequate to explain the flow and the thermohydrodynamical phenomena referred to above. In the neck of the flask (Fig 1) there can exist simultaneously currents of the same liquid flowing in opposite directions. The current flowing into the flask will not be affected by friction in its passage through the stream of outgoing helium, and when it reaches the heater it will be transformed into a normal liquid. The vane is thus capable of detecting the normal liquid but not the super-fluid helium.

Fig 3

The mechanism of the conduction of heat is to be understood as an abnormal type of convection process which arises from the fact that to bring helium from the state of zero entropy into the normal state a quantity of heat must be expended. A rough analogy may be drawn with the contrary streams of cloaked and uncloaked people which can be imagined as moving along the passage-way to the cloak-room of a theatre. Those that are dressed for going out will represent the normal atoms of helium, which have received the energy they require from the heater (the cloak-room), and those that are uncloaked will represent the super-fluid helium atoms. Unfortunately, the analogy is far from complete, seeing that the atoms of helium in the state of zero entropy pass by their fellows who are in the normal state without any interaction, while those people who have not yet obtained their cloaks could not manage in any circumstances to keep moving through the crowd without frictional resistance.

The theory explains also why the leakage of helium through a narrow opening produces a temperature difference. Helium in the super-fluid state passes through the opening more easily than helium in the normal state. Thus there occurs a peculiar type of filtration. In the liquid which has passed through there is a greater concentration of super-fluid helium, and this corresponds with such a concentration as would presume the attainment of a certain lower temperature.

In many ways experimental work, quantitative as well as qualitative, is in agreement with the theory. Some phenomena are unexplained as yet. The theory indicates that there should be simultaneously two different speeds of sound in liquid helium. There is at present no proof of this experimentally, and, moreover, the theory does not account for the critical speed which is actually observed. Further work on the elucidation of the strange phenomena of helium II is likely to prove of considerable interest.

antigenic specificity of different structural components of organs was proved, for example, in the case of the central nervous system. Also, it was demonstrated that the serum of rabbits may be caused to yield a positive Wassermann reaction by injecting the animals with a mixture of alcoholic extract of rabbit's tissue along with a foreign protein such as pig's serum, the latter being necessary to act as a 'carrier' on the analogy of Lansteiner's observations. Further researches illustrated strikingly how an antigen might be 'masked' in tissues or might fail to develop antibodies owing to the 'competition' of another antigen present along with it. *Inter alia* it was shown that an animal might come to produce antibodies to tissue constituents of its own species. The implications of those attractive observations in connexion with pathology have not yet been fully explored.

The distribution and properties of the antigens associated with the human blood groups were also extensively examined by Sachs, and his communication to the Royal Academy of Medicine in Ireland in 1939 (*Irish J. Med. Sci.*, April 1940) is a most comprehensive and readable account of knowledge on the subject up to that date.

Sachs was a man of genial outlook whose appreciation of the work of others was exercised without respect of academic or racial distinction.

C. H. BROWNING

OBITUARIES

Prof. Hans Sachs

PROF. HANS SACHS died in Dublin on March 23, with him ends the direct line of great serologists which arose under P. Ehrlich. Sachs was born in Kattowitz, Upper Silesia, in 1877. After completing his medical training he went in 1900 to the Institut für Experimentelle Therapie at Frankfurt-on-Main, where he soon proved to be a most able worker on problems of serum-haemolysis and allied studies.

When Ehrlich's chief interest shifted to cancer research and chemotherapy Sachs continued in his original field of investigation, of which he soon was the acknowledged authority. He became professor and head of the Department of Experimental Biology at the Frankfurt Institute, of which, after Ehrlich's death, he was for a time deputy director. In 1920 he went to the University of Heidelberg as professor of immunology and serology and director of the scientific department of the Institute for Experimental Cancer Research. The wide esteem in which he was held was manifested in the work entrusted to him on the serodiagnosis of syphilis for the League of Nations' Commission.

In 1908 Sachs was one of four who founded and edited the *Zeitschrift für Immunitätsforschung*. His association with this journal, now in its eighty-sixth volume, was terminated by State policy in 1935, and he also ceased to hold his post at Heidelberg. Then the Irish Medical Research Council and the hospitality of Trinity College, Dublin, enabled him to continue his work in the School of Pathology there. In addition to valuable contributions of a practical nature—the Sachs-Georgi reaction is known throughout the world as one of the first simple and reliable flocculation tests for the diagnosis of syphilis—he and his fellow-workers carried out a long series of important investigations on the antigenic properties and specificity of tissue constituents, especially those which can be extracted by alcohol (lipoids). The work appeared mainly in the *Zeitschrift für Immunitätsforschung*. The

Miss Phyllis Kelway

THE death of Phyllis Kelway on April 14 at the comparatively early age of thirty-nine comes as a shock to those who knew her as one of the small band of naturalists interested in British mammals, in particular the smaller species, such as the mice, voles and shrews. It was her probably unique distinction to have bred that smallest of living mammals, the lesser or pigmy shrew, *Sorex minutus*, in confinement, also that tiny mammal, the harvest mouse, *Micromys minutus*. She kept and studied most of the British mammals, having marked success with that delightful but difficult species, the red squirrel, *Sciurus vulgaris leucourus*, her pets "Jennifer" and "John" mating and bringing up a litter of young ones. It is noteworthy that Miss Kelway failed to get the red squirrel and the grey squirrel to take any interest in one another, her experiments supporting the view that they never fraternize, still less hybridize.

Miss Kelway wrote several books setting forth her observations and experiences, "Swift Movement in the Trees" telling of squirrels, shrews and many other creatures, while in her last book, "The Ark", she dealt with another theme, the difficulties of a smallholder in war-time. She illustrated her writings both in the Press and in book form with photographs from her own camera, for she was a skilled and charming photographer. She was born in Somerset, but lived in Yorkshire, at Almondbury near Huddersfield.

FRANCES PITT

WE regret to announce the following deaths:

Dr. K. J. W. Craik, director of the Applied Psychology Unit of the Medical Research Council, on May 7, aged thirty-one.

Prof. Thomas J. Nolan, professor of chemistry since 1932 at University College, Dublin, on March 12, aged fifty-six.

NEWS and VIEWS

Geological Survey of Great Britain

Sir Edward Bailey, F.R.S

SIR EDWARD BATTERSBY BAILEY, who has just retired from the directorship of the Geological Survey Museum, joined the Scottish Branch of the Survey in 1902, at the age of twenty-one, and rapidly established an international reputation as a leading authority on the tectonics of the Scottish Highlands. He served with distinction throughout the War of 1914-18 and after the conclusion of hostilities became in 1919 district geologist in charge of the West Highland and Ayrshire work. An outstanding achievement during his tenure of this post should be mentioned, namely, the preparation of the classic memoir on the Tertiary igneous rocks of Mull (1924). In 1929 he resigned, on his appointment to the chair of geology at the University of Glasgow, but he returned to the Survey as director in 1937.

The short period from 1937 to the outbreak of the present War saw the inception of comprehensive plans for field-work to accelerate the mapping of districts urgently requiring revision. Sir Edward's directorship will, however, be remembered chiefly for the notable part he and his colleagues played in carrying the war effort, especially during the early critical years. When the events of 1940-41 made it necessary to develop the country's mineral resources to the utmost, he threw himself with characteristic energy into the task of carrying out an immediate investigation into the available supplies of such essential raw materials as iron ores, bauxite, limestone, lead, zinc, tin and copper ores, feldspar, and silica sands suitable for optical glass. He

extended and amplified the Survey's investigations into underground water supplies throughout Great Britain, and carried through the preparation of a large series of war-time pamphlets in which the results of Survey work were made easily and rapidly accessible. In addition, Sir Edward and his staff were able to give assistance in many engineering projects directly connected with the war effort, such as the siting of aerodromes, camps and emergency hospitals, the provision of underground storage, and selection of localities suitable for opencast coal production. He has also collaborated closely with Government departments concerned with post-war reconstruction and industrial development. All these varied activities he has pursued with energy and success, and the results may be said to have demonstrated anew the importance of the part which geology and geological research can play not only in the emergency of a country at war, but also in the no less urgent problems of the years of peace ahead. Dr F. P. McLintock, deputy director, is at present in charge of the work of the Geological Survey and Museum.

Howard Florey, F.R.S : Lister Medallist

THE Lister Medal for 1945 of the Royal College of Surgeons of England, which is awarded in recognition of distinguished contributions to surgical science, has been granted to Sir Howard Florey, professor of physiology in the University of Oxford, for the outstanding importance to surgical science of his work on penicillin and its application. He will deliver the Lister Memorial Lecture later in 1945. This is the first occasion of the award, which is made by a committee representative of the Royal Society, the

Royal College of Surgeons of England, the Royal College of Surgeons in Ireland, the University of Edinburgh and the University of Glasgow.

Treatment of Leprosy

A NEW treatment of leprosy reported from Madagascar (*Brit. Med. J.*, 338, March 10, 1945, and *Lancet*, 357, March 17, 1945) suggests that it is, in some respects, a considerable advance in the fight against this ancient and terrible scourge of mankind. Drs Boiteau and Grimes extracted, so long ago as 1937, a new glucoside from the umbelliferous plant *Hydrocotyle asiatica*, which gave encouraging results when it was tried for the treatment of leprosy, but it was too toxic. In 1938 Bontemps, working at Antananarivo, isolated another new glucoside which he called 'asiaticoside', and this was not only active against leprosy but was also much less toxic. It was insoluble in water, slightly soluble in alcohol and very soluble in pyridine. Later Boiteau obtained a solution of it suitable for injection, and Devanne and Razafimahery have studied its chemical constitution. Boiteau and Grimes think that it acts by dissolving the waxy covering of *B. lepræ*, so that the bacillus then becomes very fragile and may easily be destroyed by the tissues or by some other drug. The results of injections of the solution prepared by Boiteau are reported as being remarkable. Leprosy nodules are broken down, diffuse infiltrations disappear, perforating ulcers and lesions on the fingers heal and, most remarkable of all, eye lesions are rapidly cured if treatment is given before the posterior chamber of the eye is involved. If fuller reports of trials on a larger number of patients substantiate these claims, and if asiaticoside can be prepared in sufficient quantity, mankind will owe a great debt of gratitude to the discoverers of this remedy. If the view that it acts by dissolving the waxy coating of the bacillus is correct, it is not inconceivable that it may show the way towards the control of infections with other bacilli which have a waxy envelope, such as the bacillus of tuberculosis.

Historic St. Andrews and its University

THE year 1754 gave promise of being an important one in the annals of Scotland, for it saw steps taken to found the Edinburgh Society for the Encouragement of Arts, Sciences, Manufactures and Agriculture. Within a decade, however, the Society had metamorphosed into a Society for Promoting the Reading and Speaking of the English in Scotland, which led to a fate justly deserved. But according to Prof. John Read, in the second edition of his pamphlet "Historic St. Andrews and its University" (W. C. Henderson and Sons, Ltd., St. Andrews, 1945), 1754 also saw a more enduring and certainly much more influential society formed by twenty-two "Noblemen and Gentlemen, being admirers of the ancient and healthful exercise of the Golf", namely, the Royal and Ancient Golf Club—legislative authority of the game. By that time, however, the University of St. Andrews, junior only to Oxford and Cambridge in Great Britain, was more than three centuries old, with a tradition and setting that make St. Andrews "at once the Canterbury and the Oxford (or Cambridge) of Scotland".

It is not surprising, then, that we learn from Prof. Read that the tomb of the founder of St. Salvator's College, erected in 1458, is "probably the finest specimen of mediæval work in Britain" and that the silver gilt College and Faculty maces are "older than

even the oldest of the English maces", and that the Natural Philosophy (*anglicé* Physics) Department houses the finest extant Elizabethan scientific instrument, Humphrey Cole's great astrolabe (1575). At their best, Scottish professors of chemistry have been men of erudition, and Prof Read, present director of the Chemical Research Laboratories at St Andrews, maintains that valuable, if passing, tradition. Not a few who have never heard of terpenes may be inspired by his pamphlet, if they are fortunate enough to see it, to make a post-war pilgrimage to the "little city, worn and grey".

Relation of Meteors to Short-Wave Radio 'Whistles'

A NOVEL explanation of some peculiar whistles audible under certain conditions in short-wave radio receivers is put forward by S R Khastgir (*Indian J Phys*, 17, 239, 1943). Weak short-lived whistles of rapidly descending pitch have been noticed at the Delhi receiving station of All-India Radio when a receiver is tuned to the carrier wave of the nearby short-wave transmitters. Two possible explanations are offered, in both of which the phenomenon is attributed to the entrance of a meteor into the earth's upper atmosphere. In the first, the meteor is supposed to produce a rapidly moving mass of ionized air at its head. This local Heaviside layer scatters the incident radiation from the transmitter, the rapid descent causing a Doppler change in the frequency of the scattered waves. These then interfere with the ground waves reaching the receiver, and an audible beat note is produced. As the descent is retarded by atmospheric resistance the Doppler shift lessens, and the pitch of the whistle drops. On a carrier wave of 7 Mc/s a whistle starting at 3,000 c/s would be caused by a meteor with a maximum velocity component of 64 km/s towards the receiver—not an unreasonable value.

The second hypothesis supposes that the retardation of the meteor in the ionosphere produces, in some way, an electrical impulse similar to audio-frequency static. The Fourier components of this impulse, transmitted at different velocities through the ionosphere, will reach its lower fringe in succession (the shorter waves first) and will modulate the scattered carrier waves at a frequency which is a function of time. A receiver tuned to the carrier will thus reproduce a whistle descending in pitch at a rate which should depend on the ionization. Test experiments will no doubt distinguish between these hypotheses, but there seems no doubt about the observed facts—that the whistles frequently coincide with observed meteors, and that they occur most often in the early morning, when the number of meteors is a maximum. They are thus likely to be of fundamentally meteoric origin whatever may be the details of their production.

Polish Science and Learning

THE fourth number of *Polish Science and Learning*, the series of booklets edited by the Association of Polish University Professors and Lecturers in Great Britain, is a specially educational issue. Several preliminary articles are contributed by American and British writers. Dr Maxwell Garnett's theme is English education in relation to international problems. The makers of the Paris Peace, a quarter of a century ago, he says, took no account of education and little of economics, but relied on political pacts, unsupported by the thoughts and feelings of average citizens. All

will agree that we must do better this time, though all may not agree with the details of Dr Garnett's way of doing it. Prof Powicke's article, though written for a different occasion, is wisely included because of its explanation of Oxford's peculiar contribution to English life, the claims of mere learning being subordinated to the service which learning can render to English society. We may be amateurs but we are not pedants.

The main body of the booklet, contributed by Polish authorities, makes sad reading, because every aspect of education is necessarily treated from a pre-war and the post-war points of view. In other words, the writers describe what has been ruthlessly and completely destroyed, and proceed to describe the immense task of reconstruction which faces Poland of the future. No aspect of education seems to have been omitted by the editorial committee. Among the subjects of the articles are elementary schools, secondary education, the training of teachers, technical schools, university education, scientific and technical research, books and libraries, adult education, art education and physical education. The concluding 'Chronicle' is a useful addition to a very comprehensive report on the educational situation in Poland.

Blind Workers in Industry

CERTAIN occupations such as basket-making, mangle and telephone-exchange operations have been assumed to be almost the only possibilities for the blind, and the normal factory environment has been dismissed as unsuitable. Since the need for labour during the War, many firms have experimented with a few blind workers, and a study of 215 blind workers employed in different firms has been made by K G Fenelon, of the University of Manchester. Industries included, among others, general electrical engineering, aircraft, metal ware, wood-work. 104 of the workers were trained by the firms themselves on the factory premises, 53 by the Institute for the Blind, 2 by an education committee, 8 their own homes, while 48 had no specific training but obtained their experience on the job. The firms who have experimented with blind workers report that, while some fall short of the production obtained by the fully sighted workers, yet some are quite up to normal standards and also that they are no more liable to accidents than other workers. Some involve the provision of special aids, but others can be undertaken by them with the ordinary machine. They are particularly successful in work where delicacy of touch compensates for inability to see. It is therefore important that the jobs selected for them should be suited to their particular abilities. Their concentration on the job in hand is good, and they are in general keen and industrious. One difficulty is that they are apt to get irritated by any hoarding of material. It seems clear even from this limited survey that there is a case for a comprehensive research into the possibilities for the blind. Apart from their potential value as workers, it would be an advantage to them to form part of an ordinary community.

Rickettsiasis in Brazil

THE January issue of the *Boletín de la Oficina Sanitaria Pan-Americana* contains an interesting review of this subject by Dr Otávio Magalhães, member of the Pan-American Typhus Committee.

st of the information concerns the State of Minas Geraes, Brazil, where Rocky Mountain spotted fever apparently existed for some time. There are four usual forms of the disease: inapparent, mild, benign and fulminating. It seems that there is only one virus, but probably there are various strains which may be differentiated by proper tests. The demiological nature of the infection in some parts of Minas Geraes is quite different from that of Rocky Mountain spotted fever in the United States.

Tables of Bessel Functions

THE Committee on Mathematical Tables of the National Research Council was advised that there was a great need for a modern "Guide to Tables of Bessel Functions", as there is scarcely a single field of applied mathematics in which these tables are not used. After more than a year of preparation, this "Guide" was compiled by Prof. H. Bateman and R. C. Archibald, using material on which the former had been working for many years. It has been published as a special number, occupying 104 pages, of the journal *Mathematical Tables and other Aids to Computation* (1, 205, 1944, Washington, D.C.: National Research Council. 175 p. 10s). There are two parts, one in which tables and graphs are listed with their authors, and another consisting of an alphabetical bibliography of the authors. In some places there are important formulae and explanations of how to use them. The notation has been chosen so as to agree so far as possible with that used by English authors. In addition to giving references to all published tables of Bessel functions, the authors endeavoured to add details of every known unpublished table, but unfortunately the comprehensive Liverpool "Index of Mathematical Tables" prepared by A. Fletcher, J. C. P. Miller and Rosenhead was not available, even in proof, until it was too late to give more than a cursory reference, so it was then found that the "Index" referred to more than thirty manuscript tables unknown to the reader. The second edition of Watson's "Bessel Functions" appeared too late to be mentioned. A notable feature of the "Guide" is the information concerning all known errors in the tables mentioned. A number of errata lists appear in print for the first time.

Radiant, Dielectric and Eddy-Current Heating

A PAPER on the place of radiant, dielectric and eddy-current heating in the process-heating field was read recently in London before the Institution of Electrical Engineers by Messrs. L. J. C. Connell, O. W. Humphreys and J. L. Rycroft, in which the authors maintain that if the fullest advantage is to be gained in the rapid developments which have taken place in connexion with radiant and high-frequency methods of heating, care must be exercised in the selection of the applications for which they are recommended. Although many processes can be carried out more effectively by the new methods, there is still a very real place for contact and convective heating. The purpose of the paper is to facilitate this selection. The paper first reviews the various methods of heating, indicating the physical laws and practical considerations by which they are governed and the types of heating which may be obtained. The types of application for which each process is best suited

are then classified in terms of their technical requirements. Finally, several applications are considered in some detail, and it is shown that processes having superficial similarity may nevertheless possess features, not at first apparent, which are of sufficient importance to warrant the use of different methods of heating.

The Earthquake at San Juan, January 15, 1944

HORACIO J. HARRINGTON, professor of geology at the University of Buenos Aires, has described some of the effects of this earthquake ("El Sismo de San Juan del 15 de enero de 1944", *Cronica Investigacion*, Jan 1945). The shock occurred at 19h 46m 29s without any previous warning and attained a maximum intensity in a few seconds, ending suddenly about 15 seconds after the first shock. The first shock was from below upwards, and in a few seconds afterwards a new shock took place in a horizontal direction and of an undulatory nature, from west to east. When the tremors had ceased, some 90 per cent of the buildings in San Juan had been totally or partially destroyed. The depth of focus was 14 km, with a probable error of 3 km, and the epicentre included the zone extending north from San Juan to Chimbass and Albardón. The intensity of the San Juan earthquake was IX on Sieberg's scale, and so was not excessive, nevertheless the destruction was very much greater than would have been expected. Out of a total population of seventy to eighty thousand, about eight thousand were killed and twelve thousand injured, the disproportion between the intensity of the earthquake and the destruction effected is obvious. The loss of life in the San Juan earthquake was due to the buildings being made with unbaked bricks of clay, these should be avoided in reconstruction. In addition, many of the cities of the country are built at the foot of high mountain ranges, and zones of fracture render their existence more or less precarious.

Announcements

SIR JACK DRUMMOND, chief scientific adviser to the Ministry of Food, has been appointed to the post of director in charge of the whole of the scientific research of Boots Pure Drug Co., Ltd. Sir Jack Drummond has resigned the chair of biochemistry at University College, London, which he has held since 1922, but he will not take up his new appointment until the food situation has improved.

THE Council of the University of Sheffield has accepted a gift of £1,000 from Dr S. B. Bagley, chairman of the Glass Delegation, to provide a fund for research purposes within the Department of Glass Technology.

The Medical Research Council has offered to establish a Biochemical Research Unit in the University under the direction of the professor of biochemistry, and the University Council has accepted the offer.

The Council has made the following appointments: Dr B. M. Lang, at present lecturer in charge of the Department of Philosophy, to the newly instituted chair of philosophy; Major F. W. Shotton, to the chair of geology in succession to Prof. W. G. Fearnside, on the retirement of the latter; Mr A. M. Woodward, at present lecturer in charge of the Department of Ancient History, to be reader in ancient history and archaeology, and head of the Department of Ancient History.

Application of the Chemiluminescence Test for Hæmatin to Plant Tissues

CYTOCHROMES and other catalysts capable of yielding hæmatin are widely distributed in living tissues. It is, therefore, possible *a priori* that many tissues will give a positive reaction in the luminescence test with *o*-amino phthalic acid cyclic hydrazide ('luminol') when treated in some way which will lead to the formation of hæmatin. However, in the forensic application of the test it has generally been found that vegetable matter, either fresh or rotting, gives a negative reaction¹.

The confirmation by Keilin and Wang² of the hæmoprotein nature of the red pigment of the root nodules of leguminous plants, and their identification of this pigment as a hæmoglobin, prompted an examination of the chemiluminescence reaction of nodular tissue.

The reagent was made by dissolving 100 mgm luminol and 5.0 gm Na_2CO_3 in 100 ml water and adding 20 ml. H_2O_2 (10 vol approx.) just before use. The very faint inherent luminescence of this solution was not regarded as sufficient to interfere with the reactions now described.

Solutions for test were then prepared as follows (A) 4 ml water + 1 ml 5 per cent NaOH (B) 50 mgm fresh root nodules (*Trifolium hybridum*) ground with 1 ml 5 per cent NaOH and diluted with 4 ml water (C) 50 mgm fresh leaf tissue, from the same plant, ground with 1 ml 5 per cent NaOH and diluted with 4 ml water (D) 50 mgm fresh nodules, also from the same plant, dried in the steam oven and then extracted by grinding with 5 ml. water.

3 ml portions of these test solutions were then added in the dark to 5 ml portions of the reagent in test tubes. The reactions were as follows (A) No reaction. On adding extra NaOH solution, no change (B) An intense and vivid whitish-blue luminescence. This faded gradually, but addition of extra alkali gave a perceptible brightening of the fading luminescence (C) A faint increase over the inherent luminosity of the reagent, the colour being altered somewhat by the presence of chlorophyll derivatives. Little, if any, change on adding extra alkali (D) A strongly positive reaction, similar to that given by solution (B) but not nearly so intense. On adding extra 5 per cent NaOH to the fading solution, the luminescence increased so as to become much stronger than initially. Fading did not seem so rapid as in the case of solution (B).

The observations were then extended to solutions of (E) 50 mgm stem tissue and (F) 50 mgm root tissue, also from *T. hybridum*, and of (G) 50 mgm potato tuber, each being ground with 1 ml 5 per cent NaOH and diluted with 4 ml water. These solutions reacted to the test in the same way as the leaf tissue solution (C), except that secondary addition of alkali decreased luminescence. A water extract of fresh nodules (H) behaves in the same way as the water extract of dried nodules (D).

These observations are consistent with the hypothesis that the most powerfully reacting compound in the plant tissues examined is the hæmoglobin of the root nodules, and that other compounds capable

of yielding hæmatin are present in concentrations too minute to afford amounts of hæmatin capable of giving a strong reaction under the specified conditions. The results of tests (D) and (H) are consistent with the hypothesis that hæmatin forms during grinding with water or drying is too slow to give a really intense reaction, but that subsequent addition of alkali splits off the prosthetic group of the hæmoglobin from the protein moiety and leads to the production of hæmatin so as to give a stronger reaction than initially.

It is possible that the chemiluminescence test may be of use as a rapid sorting test for locating in plant tissues unusual concentrations of substances capable of yielding hæmatin, or for the demonstration of hæmoglobin in leguminous root nodules where adequate spectroscopic equipment is not available.

I wish to thank Prof D. C. Harrison for his advice on various possible interpretations of the reaction.

Electrophoretic and Enzymatic Fractionation of Casein from Human Milk

SOME years ago I examined electrophoretically casein from cow's milk. It was established that the protein is not homogeneous¹. The electrophoretic diagram showed three different boundaries which were assumed to correspond to three casein fractions α -, β - and γ -casein. The fastest moving of the α -fraction, was isolated, and on analysis nitrogen/phosphorus ratio was found to be higher than that of total casein.

It has been considered worth while, especially in view of the importance of the organically bound phosphorus for breast-fed babies, also to examine human milk casein for the existence of electrophoretically separable fractions and their phosphorus content.

As may be seen from the accompanying record the electrophoretic pattern of human milk casein is similar to that of casein from cow's milk. The

peaks are shown. The two which move quickest no doubt represent two definite fractions of the casein. The third peak might, at least in part, be due to a δ -effect. The same may also be true of the γ -fraction of cows' casein. As is shown in Table 1, its mobility is very low in different buffers. The α -casein from human milk also shows a higher phosphorus/nitrogen ratio than the original casein (Table 2). Thus, casein from human and from cow's milk is similar in this respect. However, the difference in phosphorus content between α -casein and the original casein is more pronounced for human milk casein.

Casein 2	15.11	0.47
α -casein 1	—	0.95
β -casein 2	—	0.87

Trypsin- and pepsin-resistant fractions of casein from cow's milk) with relatively high phosphorus content have been isolated by several authors.² In order to find out whether this ferment-resistant fraction of casein is identical with, or a part of, the δ -casein (which might be expected from the high phosphorus content of the ferment-resistant fraction) the progress of pepsin and trypsin digestion on casein from human and cow's milk respectively has been followed electrophoretically. It has been found that the α -component disappeared even during pepsin hydrolysis, and no demonstrable component of higher mobility was formed. Following the method of repARATION of Damodaran and Ramachandran, it has also been possible to prepare enzyme-resistant phosphopeptide from human milk casein. In the sodium salt of this, the phosphorus content was 28 per cent and the nitrogen content 6.57 per cent.

Electrotonus in Colour Vision

DURING the past year, we have studied the influence of a weak constant electrical current upon the foveal (colour) sensitivity of the human eye. The foveal sensitivity was measured in respect of monochromatic lights of different wave-lengths. Two silver electrodes were used. The indifferent one was put on the observer's hand, the second—the different one—being applied to the contralateral eyeball of the observer or (in some control series) on his temple near the lateral angle of the eyelids. The current used always had a strength of 0.2 mA. Our experiments, in which we determined the threshold

values for foveal sensitivity, were carried out during 50–60 minutes of dark adaptation. At about the thirtieth minute of dark adaptation, when the foveal sensitivity reached its maximal stationary level, we switched on the current and allowed it to remain on for 4–5 minutes. During that period of electrical stimulation we determined the thresholds of the foveal sensitivity two or three times.

The sensitivity was calculated as the reciprocal of the transparency of the corresponding part of the absorbing photo-wedge used to alter the intensity of the monochromatic light stimuli. The sensitivity changes under the influence of applied constant current were indicated by the ratio S_2/S_1 , where S_2 is the foveal (colour) sensitivity of the eye found at the third minute of electrical stimulation, and S_1 is the same sensitivity determined just before the current was switched on. Five persons with normal colour vision took part in our experiments as observers. The data obtained are plotted on the accompanying graph. The values of S_2/S_1 are shown as ordinates, the wave-length of stimulating light, in $\text{m}\mu$, as abscissa. A -curves relate to the readings made when the positive electrode was in contact with the eyeball (anoelectrotonus), the K -curves indicate the changes in sensitivity found in the case when the negative electrode was on the eye (cathelectrotonus).

From the graphs, it can be seen that under the influence of anoelectrotonus and cathelectrotonus the changes in foveal (colour) sensitivity of the eye are of quite an opposite character. In the case of anoelectrotonus, the sensitivity for the blue-green rays of the spectrum heightens, while the sensitivity for the orange-red rays of the spectrum diminishes. In

the case of cathelectrotonus, the sensitivity for orange-red rays is heightened and for the blue-green rays lowered. In both cases there are three regions in the spectrum which have shown no changes at all in response to the electrotonic stimulation used in our experiments. These regions are the two ends of the spectrum, red and violet, and the zone of yellow near 570 m μ .

After switching off the stimulating current we observed, as a rule, changes of foveal sensitivity, which were the inverse of those found while the stimulating current was on. After four or five minutes of electrotonic stimulation, the sensitivity of the eye continued to be different for about twenty to thirty minutes.

The effects described above can be explained on the basis of the well-known ionic changes in the living tissues caused by a constant current, namely, the relative heightening of the potassium ion concentration near the negative pole and the relative heightening of the calcium ion concentration at the positive pole. It is also well known that potassium and calcium are in many physiological respects as antagonistic. At the same time, the action of potassium ions resembles the stimulation of the parasympathetic part of the autonomic nervous system, whereas the action of the calcium ions is like stimulation of the sympathetic nerve¹. Thus, our experimental observations relating to the dependence of our colour vision on electrotonus may also suggest its dependence on the autonomic nervous system as recently suggested by one of us².

Augmentation of Thyrotrophic Activity

THE following observations were made during pilot investigations on the purification of thyrotrophin from acetone-dried ox pituitary. An aqueous alkaline (pH 9-10) extract of the dried gland (from which some inactive material had been removed by isoelectric precipitation at pH 5) was brought to pH 2 with salicylsulphonic acid. The thyrotrophic activity was divided between the precipitate and the supernatant fluid, each of which apparently contained 100-200 per cent of the original activity. This was shown in three separate experiments. The third experiment showed the least augmentation, which was unfortunate, as it was carried out to test the effects of dialysis (20 hr through collodion) on the augmenting substance. The results, at least for the supernatant fluid, suggest that the augmenting substance is dialysable, though the small augmentation observed and the few animals used in the test do not establish this statistically.

The results recorded in the accompanying table show the weight of guinea pig thyroid glands (adjusted for body-weight differences) after the injection of doses equivalent in each case to 300. mgm of the

original dried pituitary. The tests were carried out on groups of three animals according to the method of Rowlands and Parkes¹.

Expt	Wt of thyroid gland $\pm$ s.e. (mgm)		
	Original Extract	Salicylsulphonic acid	
		Supernatant	Precipitate
1	30 $\pm$ 3	61 $\pm$ 5	65 $\pm$ 9
2	30 $\pm$ 2	63 $\pm$ 10	58 $\pm$ 6
3 normal dialysed	28 $\pm$ 4	35 $\pm$ 5	27 $\pm$ 6
	28 $\pm$ 2	26 $\pm$ 3	26 $\pm$ 3

Weight of thyroid in 11 un.injected animals = 15 $\pm$ 2 mgm

We have had no opportunity of investigating this matter any further, but assume that the augmentation is caused by delayed absorption from the injection site, since such effects of contaminants have been reported for many other biologically active substances. The effect, whatever the cause, must obviously be taken into account when impure thyrotrophic extracts are assayed by methods using subcutaneous injection.

Structure of Wharton's Jelly

Baechich and Riddell¹ have recently discussed the nutrition and structure of Wharton's jelly of the umbilical cord. Their letter was prompted by the description by Barcroft *et al.*² of a non-vascular circulation through the cord from placenta to foetus. Baechich and Riddell compare the avascular nature of cornea, cartilage and Wharton's jelly and suggest that their nutrition must be similar, they conclude that the non-vascular circulation may contribute to the nutrition of Wharton's jelly itself. They point out that cornea, cartilage and Wharton's jelly all contain similar metachromatic substances and say "It appears justifiable to suppose that the substance responsible for the specific (metachromatic) staining reaction is either heparin, which is a mucopolysulphuric acid or a chemically allied substance because only these substances give a metachromatic staining reaction with toluidine blue".

We would like to direct attention to the work of Meyer and his colleagues^{3,4,5,6} in America, and McClean and his colleagues^{7,8} in Great Britain, who have shown that the acid polysaccharide, hyaluronic acid, is at least a major component of Wharton's jelly. This polysaccharide, which is apparently composed of equimolar parts of *N*-acetyl glucosamine and glucuronic acid³, is widely distributed as a constituent of synovial fluid⁴, cornea⁵, vitreous humour³, skin⁵, muscle¹⁰, the cumulus cells and corona radiata of the unfertilized ovum¹¹ and the capsules of certain groups of streptococci^{12,13,14}. Meyer and Chaffee state that the hyaluronic acid of the cornea and skin exists as the sulphuric acid ester. It is known that hyaluronic acid forms an insoluble complex with toluidine blue, but according to Meyer and Chaffee does not stain metachromatically whereas the sulphuric acid ester does. We would also direct attention to the exhaustive studies of Lison¹⁵ on metachromatic

ains and their reactions; he showed that meta-chromatic staining depends primarily upon the presence of sulphuric acid groups attached to compounds of sufficiently high molecular weight. We have found that, owing to its solubility, hyaluronic acid is removed from tissues during fixation by ordinary histological methods, and, in order to prevent this, it is probably necessary to use some such fixative as Carnoy's fluid. It is therefore probable that the hyaluronic acid had been removed from the specimens of umbilical cord examined by Bacsich and Riddell and that the metachromatically staining substance described by them was chondroitin sulphuric acid, which Meyer and Palmer consider is a constituent of the connective tissue of the cord.

Bacsich and Riddell¹, in their letter of March 3, discuss the structure and nutrition of the cornea, cartilage and Wharton's jelly, suggest that the metachromatic staining of the cornea with toluidin blue may be due to heparin or some other related compound. Jorpes, Holmgren and Wilander² briefly reported that a substance prepared from cornea which had the properties of a mucoitin sulphuric acid showed only a very weak heparin activity. They thought that this activity was due to the small amount of heparin extracted from the mast cells at the limbus, and that the general metachromasia was due to the mucoitin sulphuric acid. Meyer and Chaffee³ have since isolated a mucoitin sulphuric acid from ox cornea and shown that it is the mono-sulphuric acid ester of hyaluronic acid, the sulphate-free polysaccharide which Meyer and Palmer⁴ had isolated from Wharton's jelly and vitreous humour. They found that it is present in the cornea in a concentration of at least 1.8 per cent. They failed to isolate mucoitin sulphuric acid from the sclera, which shows metachromasia.

A sample of ox cornea mucoitin sulphuric acid (ester sulphur 4.1 per cent) was very kindly tested for heparin activity for me by Dr. MacIntosh and found to be inactive. MacIntosh⁵ compared the anti-coagulant activity of various heparins and other sulphur-containing polysaccharides with their reaction with toluidin blue. He found that the two properties ran roughly parallel, mucoitin sulphuric acid having a negligible heparin activity and a colour value with toluidin blue of about 1 per cent that of the purest heparin. In spite of the relatively weak

reaction between toluidin blue and mucoitin sulphuric acid, the concentration in the cornea is ample to account for the diffuse metachromasia. A 0.003 per cent solution of ox cornea mucoitin sulphuric acid gives an easily visible purple colour with dilute toluidin blue. There seems therefore no need to invoke heparin or some unknown substance to explain the metachromatic stain of the cornea substantia propria.

Spontaneous Transmissible Tumours in the Syrian Hamster

SINCE 1930 a large number of Syrian hamsters have been bred in the Hebrew University, mainly for work on kala-azar. All the animals originated from a single family and have been distributed to laboratories to various parts of the world. A record of spontaneous tumours in Syrian hamsters is therefore of general interest.

During the last seven years, we have noted thirteen instances of spontaneous tumours among a thousand animals, which were carefully examined since they had been used for experimental work on leprosy. In one case a polymorph sarcoma was found. This tumour has been passaged twenty-five times during the last three years by grafts, by inoculation of macerated tumour and by heart blood. It metastasizes in lymphatic glands, liver, spleen, kidney, stomach, intestines, muscles, testes and ovary. It is not transmissible by filtrates of macerated tissue. Inoculated animals survived up to five months in the first ten passages and up to two months in subsequent ones.

Another polymorph sarcoma, also freely metastasizing, was observed, and thirteen passages have been noted in sixteen months. Inoculated animals survive up to three months.

A carcinoma was discovered embedded in pancreatic tissue and was found to be readily transmissible and metastasizing in lymphatic glands, kidneys, testes, spleen, pancreas, liver and lungs. Six passages have been obtained during twenty months. The majority of inoculated animals survived up to five months but a few lived up to one year.

Cortical hypernephromas (in the adrenals) have been observed in ten animals during the last seven years; but only two have proved transmissible by subcutaneous and intraperitoneal grafts. From one tumour five passages have been obtained in four years, and from another two passages in eighteen months. Minute metastases were found in the pancreas, lymphatic glands and suprarenals but longevity was not affected.

A Hitherto Undescribed form of Adult Axis in the Genus *Batrachospermum*

THE genus *Batrachospermum* has always attracted interest as one of the few freshwater members of the Florideae and on account of its distinctive appearance. Notwithstanding a general familiarity with the external form and early development of *Batrachospermum*, it has not been recognized previously that the old axes of some species may appear 'solid' in transverse section, either all or almost all trace of the primary central filament of cells being lost. Such a condition has been found to exist in three species of this genus (Fig. 1), and there is no reason for doubting that subsequent investigation may show it to occur in other non-ephemeral species. The three species mentioned have not been identified with certainty as comparison with type specimens has been impossible in present circumstances, but two undoubtedly belong to the Helminthoidea section of the genus. Only male plants of the third species, the one here illustrated, have been seen and hence its affinity remains in doubt.

Detailed study of one of the three species has shown the steps by which this 'solid' structure is attained, and these are to be described fully in a subsequent publication. Briefly, they are as follows: branches from the filaments which corticate the central filament from quite an early age actually penetrate the cells of this central filament in a manner similar to a parasitic fungus penetrating the host. Once inside, these invading filaments grow, branch and ultimately fill the upper part of the cell completely, as is shown in Fig. 1. In Fig. 2, which is a photograph of the same cell at a slightly lower level, the cell is almost full of invading filaments cut transversely. There may be so complete a disintegration of the cell wall at the upper end that all trace of it is lost. The diameter of the basal end of the cell is always much greater than at the apical end and there the wall may remain intact or else considerable remnants are to be seen as well as a space representing the area of the original lumen of the cell, traversed by a few filaments (Fig. 3). Filaments invading the central cells may pass from cell to cell in a longitudinal direction or they may enter at one side and directly pass out at the other side.

This secondary development in the centre of the axis is usually accompanied by a proportionately greater production of secondary branches of limited growth, resulting in an evenly cylindrical thallus. These axes may be stronger than the primary

ones and hence may be of biological importance to the species.

The similarity of the general appearance of the secondary condition of the uniaxial type to the primary condition of the multiaxial type of construction in the Florideae, such as is found in *Nemalion*, is so obvious that it needs no stressing: but the fundamental ontogenetic difference between the two types remains.

Insect Transmission of the 'Swollen-Shoot' Virus in West African Cacao

DURING 1943-44, exploratory experiments were carried out at Tafo, Gold Coast Colony, to determine which insects might prove to be vectors of the well-known 'swollen-shoot' virus disease which is causing widespread destruction of native-grown cacao (*Theobroma Cacao* L.) in certain parts of West Africa, notably in the eastern province of the Gold Coast. Four recognizable 'strains' of the virus were tested separately, in the experiments, namely:

I. Virulent strain. Characterized in the infected plant by the development of pronounced swelling in the recent ligneous growth; by a typical mosaic in the foliage especially noticeable in the new leaves (flush) appearing after infection; and death within a period rarely exceeding eight months in the case of plants infected when less than two years old.

II. Non-virulent strain. Swellings only, or at most an indeterminate chlorosis, not always present, in the foliage.

III. Non-virulent strain. Mosaic (mottling) only, of a pattern distinct from that shown by I, above.

IV. Non-virulent strain. Mosaic ('feather' type) quite distinct from the mosaics shown by I and II above.

The following Hemipterous insects, all common to *Th. Cacao*, were used in the experiments:—Aphid: *Toxoptera aurantii* Boyer; Psyllidæ: *Mesohomopterus tessmanni* Aulm.; Coccidæ: *Ferrisia virgata* (Ck.) *Pseudococcus citriabilis* Laing, *Pseudococcus* cf. *Risso*.

All phases of the work, except the identification of the coccids, for which I am indebted to specialists, were carried out by me personally. Prof. G. F. Ferris kindly determined *F. virgata* and *P. citri*, the identifications of other material of these species being confirmed by Dr. W. J. Hall; while Mr. F. Laing has been good enough to describe the new species of *Pseudococcus*, which appears to be indigenous on various forest trees and shrubs in the region under the name *citriabilis*.

Successful transmissions were obtained: (a) using the mealybugs, *F. virgata* and *Ps. citriabilis* with strain I of the virus; using *Ps. citriabilis* with strain II; and (c, d) using *Ps. citri* with strains III and IV, separately.

(1) TRANSVERSE SECTION OF THALLUS OF *Batrachospermum* sp. NEAR APICAL END OF CENTRAL CELL ($\times 22$). (2) AND (3) TRANSVERSE SECTIONS OF SAME CENTRAL CELL AS IN (1), THE FORMER BEING IN THE UPPER HALF OF THE CELL AND THE LATTER NEAR THE BASAL END ($\times 400$).

lumerous experiments with the aphid and the syllid, conducted under precisely similar conditions o those with the mealy-bugs, but using much larger umbers of individuals, consistently yielded negative sults. These results are given in the accompanying ble, in which the signs + and - indicate positive r negative results, respectively, in an adequate series, f experiments

Species of insect	Strain of virus			
	I	II	III	IV
<i>Ferrisiana virgata</i>	+	-	-	-
<i>Pseudococcus eximabilis</i>	+	+	-	-
<i>Pseudococcus citri</i>	-	-	+	+
<i>Toxoptera auranti</i>	-	-	-	-
<i>Vesohomotoma lessmanni</i>	-	-	-	-

The selective results suggest that more than one stinct virus may be concerned in the complex his is also to some extent confirmed by then effects i the plant (*vide supra*)

The earliest recognizable symptoms appeared in ie experimental plants five weeks after transfer of sects from infected plants. In the course of numer- is experiments, it was discovered that strain I ould be transmitted by one individual female of s *eximabilis*, also by this mealy-bug in its young rval ('crawler') stages. In one instance transmission eurred using females of this species, which were own to have lived on the infected source plant for ot longer than forty-eight hours. To ensure trans- ission, however, a minimum of ten females, prefer- ly with accompanying larvæ, is advised, and proof required that some of them have fed on both the fected source-plant and the uninfected experi- ental plant.

The work was carried out as part of a research ogramme financed by the Colonial Development d Welfare Fund. It is hoped to publish a full per elsewhere at an early date.

Unification of the Physical Fields

SCHRODINGER has stated¹ "At the back of our iving for a unitary field theory, the great problem aits us of bringing it into line with quantum eory." With this, one may venture to differ, in o respects.

(1) Eddington answered Schrodinger's "great oblem" by bringing space-curvature into line with antum theory. He remarked² "In the theory of ativity energy and momentum are coefficients of rvature in space-time, in quantum theory they e characteristics of wave-functions in flat space is a big step towards unification of physics if we a find the precise connexion between these two ys of representing the same thing." He demon- ated that energy-momentum, usually expressed rms of curvature, can become expressed in rms of probability distribution, and thence in rms of wave-functions as in quantum theory.

(2) The problem is rather one of bringing quantum eory into line with space curvature.

The two ways of representing energy-momentum a be coalesced into a space-curvature representa- n. The steps are the inverse of Eddington's, obability distribution (wave function) is expressible

in terms of space-curvature. In this way the inverse of Schrodinger's problem can be answered, but in spite of this, he has to be content to realize¹ that he is ignoring "such features in the conventional de- scription of the physical fields as are concerned with their quantum character."

My own theory of indeterminate space-time³ is wholly inverse to Eddington's. Like Schrodinger, it uses the mathematics of relativity, and the axiom of the unsymmetrical affine connexion. Schrodinger is anxious to provide two mathematical entities in addition to the Einsteinian gravitational tensor, which are to be representative of the so-called meson field and the electromagnetic field respectively. Eddington has shown that the meson field is only an apparent but really non-existent range of the non-Coulombian interaction of two particles. My main purpose in using unsymmetrical affinity was to give the *uncertainty idea* a place in the primary axiom. For this purpose a number of components of affinity additional to those employed by Einstein was re- quired. These additional components were to carry latent in them all the potentialities of discontinuity, so necessary in connexion with quantum characteris- tics. By suitable provision at the commencement, energy-momentum, and *uncertainty*, appear as co- efficient of curvature, in quantum theory they are all three characteristics of wave-functions.

My treatment stipulates that the additional com- ponents of the unsymmetrical affinity have to be *indeterminate*. Indeterminacy has a plain connexion with uncertainty. This stipulation calls forth certain repercussions elsewhere. A most important one is the non-appearance of a meson field entity. If de- sired, one can use the extinction of the Schrodinger meson-field entity as a necessary condition dis- covering what the consequences are for the com- ponents of the affinity. Whichever way is chosen, the disposable components are indeterminate, and uncertainty unifies with the nature ascribed to space- time. This puts the meson field right out of the picture, in agreement with Eddington.

It is evident from Prof Schrodinger's work that by omitting my primary stipulation, there is obtainable a perfectly determinate space-time system, within which uncertainty, and therefore quantum theory, can find no place. (Neither does it appear that a true electromagnetic system is possible in that case, because that requires indetermi- nate potentials.)

Eddington distinguished between the abstract geometrical origin and the "physical origin" (arrived at by averaging the scatter of blurred physical land- marks), and from his studies arose a number of cor- rections of an elementary statistical character, on current inaccurate views. One such statistical in- accuracy accounts for the apparent range of the really non-existent meson field.

Indeterminate space-time retains Eddington's "physical origin" and co-ordinate system, and works with it, relegating uncertainty (scatter) to a place in the space-curvature. He called such a system "Sigma-metric." Schrodinger works with what Eddington called the abstract geometrical system. Our *physical* system cannot be compared with an academic, abstract geometry—in particular the com- mutative properties of second partial derivatives in the one has only an indirect relation to the other because the former is the subject of mathematical physics, whereas the latter is pure mathematics. It is these special commutative properties, to which I

refer, that have a direct bearing on quanta (that is, discontinuity). In my theory they give me the quantal part of the unification, in Schrodinger's, nothing, because they are in no way unusual.

A requirement in all electromagnetic problems is the proper statement of boundary conditions. So it is in respect of the energy of uncertainty. Once the boundary conditions are specified, the energy quanta become determinate. The boundary conditions for the quantal part of the problem and for the electromagnetic part are, not unnaturally, found to be the same in my analysis. This is where indeterminate theory links the indeterminism of electromagnetic potentials with the uncertainty principle of Heisenberg.

Isomorphic Relationship between Rubidium and Thallium in Igneous Minerals

V. M. GOLDSCHMIDT¹ has been able to demonstrate that the radius of an ion is a fundamental factor in regulating isomorphic behaviour, ions of like size being capable of replacing each other isomorphically within a crystal lattice. The application of this law of crystal chemistry to a study of the distribution of the elements in the earth's crust has yielded fruitful results, in particular, the behaviour of many of the rarer elements during the fractional crystallization of a magma is now reasonably well understood. For example, Goldschmidt² has pointed out that, since the radii of Rb⁺, Tl⁺ and Cs⁺ (1.49, 1.49 and 1.65 Å, respectively) are similar to that of K⁺ (1.33 Å), these elements are commonly found in potassium-rich minerals, particularly those of late pegmatitic phases.

As a result of the identity of the radii of Rb⁺ and Tl⁺, it was decided to investigate whether these two elements were quantitatively associated in igneous minerals, that is, capable of entering crystals of various types with the same facility. In all, seventy-two analyses of lepidolite (the richest mineral in both rubidium and thallium), zinnwaldite, amazonite, potash feldspars other than amazonite, phlogopite, muscovite and pollucite, have been carried out, and the analyses reveal a very close relationship between rubidium and thallium, the maximum variation of the ratio Rb₂O/Tl₂O being 35–450, that is, 10 × 1.3, with an average ratio of 135. The concentration range covered in these analyses is about a thousand, and throughout there is no apparent change in the ratio, the only apparent factor influencing the ratio being the relative initial paucity or richness of either element in a particular source.

Graphically, a plot of log per cent Rb₂O v. log per cent Tl₂O reveals that a straight line of unit slope accommodates these points most satisfactorily, that is, Rb⁺ and Tl⁺ enter crystal lattices and replace K⁺, and in the case of pollucite Cs⁺, with exactly the same facility. In contrast, analytical data on rubidium and caesium show that although these two elements

are invariably associated, the ratio Rb₂O/Cs₂O is very variable and tends to decrease with differentiation as a consequence of the larger radius of the caesium ion.

Direct evidence of the analogous isomorphic behaviour of Rb⁺ and Tl⁺ has been furnished by the analyses of more than one mineral from the same pegmatite, the ratio Rb₂O/Tl₂O remaining exactly constant.

This identity in the isomorphic behaviour of Rb⁺ and Tl⁺ during differentiation furnishes a striking and elegant example of the manner in which ionic size determines isomorphic behaviour and thus assists in regulating the distribution of the rare elements.

All the analyses embodied in the above investigation were carried out spectrographically.

Distribution of Wars in Time

A STATISTICAL regularity in the dates of wars has been brought to notice by the following numerical process. A list was prepared of wars in the world as a whole. Each calendar year was thereby characterized by the number, $x = 0, 1, 2, 3, 4$, of wars which began in it. Next, the number, y , of years which had each such character was counted. A similar procedure was applied to the beginning of peace. Here are some results:

War,	x	=	0	1	2	3	4	>4
Peace,	y	=	63	35	9	2	1	0
	y	=	62	34	13	1	0	0
	$110 e^{-\mu} \mu^x / x!$	=	62.0	35.5	10.2	1.9	0.3	0.0

where $\mu = 63/110$. The formula is the Poisson law of improbable events. Other phenomena, known to be described by the Poisson law, include the distribution in time of the alpha particles emitted from radioactive substances¹, or of deaths by kick from a horse².

This impersonal account of the beginnings of war and of peace contrasts with the personal details in the newspapers and history books. In somewhat the same manner the statistics of marriage contrast with a love-story in a biography. The Poisson law is statistical in the sense that it does not predict the date of any future peace or war.

The particular set of wars summarized in the above table are fatal quarrels, which caused from 10³ to 10⁴ deaths, and which ended from A.D. 1820 to 192 inclusive³. But the Poisson law, with other constants, also describes the beginnings of wars from A.D. 1500 to 1931, as set out in Prof. Quincy Wright's list⁴.

A more critical account of these regularities has been accepted for publication by the Royal Statistical Society.

CIVILIAN CONTRIBUTION TO EDUCATION IN H.M. FORCES

THE report of the Central Advisory Council for Adult Education in H.M. Forces for the six months ending September 1944 presents further evidence of the remarkable growth of education in the Services and of the inestimable contribution made by civilians. During the period under review (19,023 single lectures, 2,955 short courses (average number of meetings 5), 2,358 classes (average number of meetings 9), and 348 intensive schools, leader's courses and conferences, are known to have been arranged through the agency of regional committees besides these activities, other classes were arranged by local education authorities direct with the Services, while many other informal meetings are difficult to represent statistically. By far the greatest quantity of work was done for the Army, especially the Anti-Aircraft Command, but a considerable amount was done for the Navy, the Royal Air Force, and the United States Forces. Since much of the educational work is co-educational, it is difficult to show how much advantage was taken by the Women's Services of regional committee facilities, but the amount of all-women activities was approximately one-sixth of the whole.

Analysis of the subjects taken shows that, as usual, current affairs accounted for the greatest demand in lectures and short courses. Of the classes, handicrafts and languages were most popular. An illuminating comment on the work as a whole is that the number of handicraft classes continued to show substantial increases, despite the all-round tightening in the supply of tools and materials. There was an increased demand for single lectures on science topics, and a considerable rise in the number of classes in 'non-vocational' science. This interest in science was undoubtedly stimulated by those regional committees which made deliberate attempts to provide facilities and to make them widely known. The response was particularly encouraging where it was possible to cater for voluntary audiences. It is unlikely, however, that any great demand for science will be forthcoming until there are far more science lecturers and teachers who will pay at least as much attention to the presentation of their subjects as to their content.

In music, the demand continued to be for general talks and discussions, and piano and gramophone lecture-recitals, although many analytical lectures and classes in the history and appreciation of music were also held. Wherever suitable lecturers were available, the demands for drama were more than enough to keep them fully occupied. A number of lay-reading circles and speech-training classes were formed, while drama festivals were organized and assisted. Much was also accomplished at music and drama week-end schools, which are extremely popular as a voluntary activity with members of both men's and women's Services. On the arts side, the main task was in the raising and maintaining of standards, the development of creative work, and the widening of the range of crafts practised on many lines, rather than the expansion of pioneer work among the various informal activities undertaken, a widening advisory service, which was arranged by the regional committee, invites comment. This ser-

vice supplied notes on food production, as well as personal advice. 95,000 plants raised in the university botanic gardens were distributed to units taking advantage of the advisory scheme last season. These included vegetables, shrubs, herbaceous plants, alpinists and annuals, in addition to gift boxes of American vegetable seeds. Figures of produce yields are not available, but the quality of cultivation was said to be high.

Of the 348 intensive schools provided by the regional committees, 101 were residential and more would have been if accommodation had been available. Towards the end of the summer, several committees planned to provide residential hostels to be used solely for their Service work, and, during the autumn, one hostel in England and another in Scotland were opened. It would be impossible here to describe adequately the different courses held, but the following may be regarded as illustrative examples. One regional committee arranged a series of seven voluntary week-end courses in music, drama, the film, art, science, literature, and the art of living. About sixty students attended each week-end, and there were waiting lists of up to a hundred for each course. To assist in the training of teachers for the Release Period Education Scheme (*Nature*, 154, 525, 1944), five regional committees serving an Army Command arranged a series of courses, each of a fortnight in duration, in science, history, geography, literature and economics.

Perhaps the most astonishing feature of the report as a whole is that it was possible to carry on so many educational activities during one of the major climacterics of the War. For many of the committees, the period was a difficult one owing to the uncertainty of the demand from week to week. The slight decline in the number of single lectures and short courses was more than counterbalanced by the increase in the total number of classes. In many ways this was an advantage, and one committee reported that "Education in the Services has probably approached more closely to civilian peacetime adult education than before. Previously we had to maintain an uneasy balance between keeping the units amused and encouraging them to think for themselves, and since the lecturers who can do both are rare, the sheer volume of demand in the past obliged us to use (more frequently than we liked) the 'popular' lecturer for pioneer work. With a smaller demand, we have been able to use lecturers of a considerably higher standard." The Central Advisory Council, the regional committees, and all the civilians who have helped in this richly consequential work deserve the warmest commendations of a democratic country.

Service men and women at home have shown their gratitude for the work done for them by these civilians, and, to a lesser extent, those serving abroad are now being given an opportunity to share in the facilities. Recently, a scheme was started whereby prominent civilians make tours abroad to lecture to H.M. Forces. Some of these visits have been concluded with memorable results. It is pleasant to note that, during the next few months, some well-known men of science are to take part in this overseas lecturers scheme. With lessening demands on them for purposes of war, perhaps more of them will be freed to take part in this valuable work.

The report was issued by the Central Advisory Council for Education in H.M. Forces (secretary, Dr Basil A. Yeaxley) at Rewley House, Oxford.

THE DURHAM COALFIELD

THE fuel technologist, the mining engineer and the geologist will find material of interest in the Regional Survey Report on the Durham Coalfield.* The pressing needs of war have revealed serious defects in the organization and technical efficiency of British coal-mining, and the Minister of Fuel and Power has wisely decreed that the basis of any attempt to create an efficient and prosperous mining industry is a national stock-taking of the already depleted coal resources of Great Britain.

At an early stage in the report it is made clear that this coalfield has made, and will continue to make, a vital contribution to the national economy. Durham coals vary much in character, but this area is justly renowned for its coking and gas coals, described as "probably the best in Europe". In West Durham certain of the seams yield coal which produces an excellent metallurgical coke, hard in texture and low in sulphur and phosphorus—a coke in great demand for foundry and general metallurgical work. Emphasis is very properly laid on the fact that the seams yielding the best coking coals have but a limited life, and it is estimated that, at present rates of production and consumption, the total coking coal reserves will be extracted within seventy years. The conservation of these resources of coking coal is clearly a matter of first importance, and the report makes a significant reference to the considerable export trade prevailing in this class of coal in normal times. Almost the whole of the coalfield produces gas coals of good quality. Much of the coal required by the gas works of London and the south coast comes from Durham, and prior to the War, Durham coal was shipped to many of the European gas works.

There has been much speculation as to the probable life of the British coal seams, but it is certain that the regional surveys will provide data for reasonably accurate estimates. Since previous attempts to arrive at the coal reserves of Great Britain much information has been compiled by the Geological and Fuel Research Surveys, while the financial transaction involved in the nationalization of mineral royalties necessitated the preparation of proposals for working during the next thirty years, with an estimate of the reserves remaining in 1972. With certain reservations, the estimated reserves of the Durham Coalfield are given as 3,000 million tons. It appears that this is a conservative estimate, many thin and low-quality seams are not included in the figure, and it is also probable that there are further substantial reserves of under-sea coal. In 1938, the output was approximately thirty-three million tons, so that at this rate of production much of the Durham Coalfield will be exhausted in the next hundred years. Nevertheless, coal will continue to be produced from this area for a much longer period, seams not now regarded as a commercial proposition may well prove workable in the years ahead, "providing, as it were, a second harvest".

The conditions prevailing in the under-sea areas are of great importance to the coalfield. It is disappointing to read that there are deteriorations in certain seams as they pass seawards. The Durham Coalfield is apparently affected in the same way as the East Midland Coalfield, which suffers a marked deterioration in the seams underlying its eastward

extension. Exploration has been carried to a small distance beyond the three-mile limit, but it is expected that one or two of the better seams will be workable for a distance of six miles or more out to sea.

An astonishing feature of the report is the statement that some 738 million tons of coal have been sterilized for one reason or another. The bulk of the coal has been left in order to avoid damage to buildings by mining subsidence, and the report states that if arrangements could be made for supporting the surface by stowage, some 468 million tons of the sterilized coal might well prove economically workable. Since sterilized coal has not been included in the estimate of total reserves, and represents about 25 per cent of the latter figure, it is clear that the introduction of modern methods of stowage would result in a considerable addition to the resources of the coalfield. To obviate further undue sterilization of Durham coal, care is needed in the selection of sites for future houses and buildings.

The industrial life of this area is based on its high quality coal seams, and any consideration of future prospects must take into account the possibilities of using coal as a basic raw material. Included in the report is a short account of the findings of the Coal Processing Industries Panel of the North-East Chemical and Allied Industries Development Committee. It is made clear that the establishment of new coal-processing industries will involve a very large capital expenditure, and that the success of any project of this nature will be dependent on adequate co-ordination. "The Gas-Grid Scheme, the extraction of olefines, methane and other gases, the production from these of chemicals and plastics, the conversion of coke to petrol, Diesel oil and other hydrocarbons are all inter-related, and part of one comprehensive coal processing project."

The remainder of the report deals with the possibilities of de-watering a large tract of flooded coal south-west Durham, the question of increasing productivity by further mechanization of the mines, and the housing requirements of the mining community. As a guide to the present position and future of the coalfield, the report is a document of major importance, of interest to all who believe that the future of Britain is dependent on the proper use of our remaining coal resources.

H. HARTLEY

REFORM OF THE PATENT LAW IN BRITAIN

DURING the past few years, there have been many allegations that monopoly rights created by patents for inventions are being used contrary to the public interest by large industrial corporations. One suggestion which has been mooted in Great Britain for rectifying this alleged abuse is that each patent shall be granted subject to the condition that any person may obtain a licence to work the invention on terms to be agreed with the patentee or, in case of disagreement, to be settled by the Comptroller-General of Patents. This suggestion, in its original form, has not met with general acceptance, and a modification of it is put forward by Prof. Polanyi in a pamphlet reprinted from the *Review of Economic Studies*, entitled "Patent Reform: a Plan for Encouraging the Application of Inventions".

Prof. Polanyi expresses the opinion that to grant all patents subject to compulsory licensing on terms

* Ministry of Fuel and Power. Durham Coalfield Regional Survey Report (Northern "B" Region). Pp. 48. (London: H.M. Stationery Office, 1945) 1s net.

be settled by the Comptroller would produce actually the same results as if patents had been abolished altogether, he suggests an alternative system under which licensing is supplemented by Government rewards to patentees on a level ample enough to give general satisfaction to inventors and their financial promoters. In operating the system, patents would be granted by the Patent Office in accordance with the present law and, shortly after a patent had been granted, the Comptroller would lay down obligations to be fulfilled by licensees. These obligations would have only one purpose, namely, to ensure the assessment of the economic value created by the invention. Licensees would have to make returns to patentees on certain technical points designated to them and, on these returns, patentees would base their own assessment of the economic value created by the invention. The Government would undertake to pay annually to patentees a fixed fractional part—perhaps one-tenth or one-third—of the approved total of assessed values created by the invention during the previous year as an integral part of the system that public rewards could be so adjusted as to make them sufficiently attractive to inventors and backers of inventions in general. In many cases, the process of assessing the economic value of the invention for purposes of rewarding the patentees might be carried out directly.

Government inquiry, to the exclusion of any reports by licensees to patentees. It is claimed by Prof. Polanyi that under the existing system the presence of the attributes of novelty, utility and subject-matter in each invention leads to serious abuses of legalism and to consequent inequitable remuneration of inventors, and that his system would provide an equitable reward for each of the investigators taking part in the production of a patentable invention. He foresees, however, two dangers, though he is of opinion that each can be avoided. In order to obviate the danger of corruption and arbitrary oppression, which is never far removed from the grant of Government subsidies, the whole procedure of their assessment should be made fairly rigid, by requiring the returns on which they are based to include only data endorsable by accountants' certificates. Further, in his opinion, the fact that considerable sums of public money would be required under his system, in order to pay rewards to patentees, not be held against it because the burden would be more than offset by the benefits accruing to the public.

It is possible that in respect of each of these dangers Prof. Polanyi is too optimistic. The reluctance of the British Government to provide public money to produce benefits that cannot be readily shown to be due to the money so used is well known, and it is not at all certain that a Government would provide an amount of public money that would be accepted as adequate by patentees and their financial backers, and at the same time be recognized by the public as reliable.

Further, experience has shown that the danger of corruption and arbitrary oppression is not easily avoided. One outstanding example of direct government rewards to inventors is the system at present in operation in the U.S.S.R. There, a special form of patent protection was established in 1931 which entitled the inventor to receive certain fixed compensation and various living or social privileges, and which contained elaborate provisions for the testing and exploitation of inventions. On March 5, 1941,

the Council of People's Commissars of the U.S.S.R. promulgated a decree introducing a new "Inventions Statute" and repealing the former one dated April 9, 1931. The following extract from *Pravda* of April 15, 1941, stated its objects:

"The main object of the revision is to establish a definite procedure for examining and consummating inventions and technical improvements and to give a number of privileges to inventors to protect them from bureaucrats and procrastinators."

"The Statute establishes definite periods within which offers of inventions and technical improvements must be accepted or rejected, or definite tests inaugurated. The reason for these rigid regulations is that we have not yet got rid of our bureaucrats, who beat off inventors like importunate flies. There are inventors who for five years have been sitting on the doorsteps of commissariats, trusts, newspaper offices and complaints offices in a vain endeavour to get an answer as to the fate of their proposals."

Even if Prof. Polanyi's hope of avoiding these dangers is realized, it is not clear how his system will overcome the fundamental difficulty raised by compulsory licensing of all patents. So far as Great Britain is concerned, after an inventor has obtained the grant of a patent, either he or his financial backers must provide the capital necessary to work the invention in this country on a commercial scale if it is desired to retain the monopoly. If the monopoly is lost by compulsory licensing, the difficulty of providing this capital will be increased, for not many inventors or their financial backers will be prepared to erect plant for the commercial exploitation of an invention with the risk that it may be a failure, if their competitors are at liberty to obtain a licence should it be a success.

CAROTENE AND SUGAR CONTENT OF CARROTS

THE nutritional value of carrot roots is due largely to their contents of carotene and sugar, and both these constituents are most abundant in the phloem. It is of interest to note, therefore¹, that although the phloem constitutes more than 60 per cent of the root the proportion is greatest in young roots, although carotene content increases with maturity but is least in 'large strain' carrots². Carotene content is influenced by manuring, but carotene losses during storage are negligible until the stored roots sprout in the spring. Although sugar content is often a good index of 'quality', the correlation between desirable taste and refractive index of the juice is often upset by the presence of an unidentified bitter constituent³.

Maintenance of high quality (that is, high sugar stocks) may be difficult, as these roots when replanted for seed production often rot and so fail to produce a satisfactory crop of seed⁴. Seed production, too, may be complicated by the temperature requirements of the carrot⁵, H. S. Sakr and H. C. Thompson reporting that the initiation of flower primordia is inhibited at temperatures in excess of 70° F. although doubtless the critical inhibiting temperature is influenced by the previous history of the carrot.

Not less important than the taste and sugar content is the shape of the roots, and traditionally carrots are grown on land "manured for a previous crop", fresh animal manure being thought to induce

branching or forking of the roots G J Raleigh⁶ reports, however, that with carrots in sand culture supplied with a complete nutrient solution, the addition of cow manure free from urine did not increase the amount of root branching, but cow or horse urine did cause forking. Attempting to discover what substances were responsible for this effect, Raleigh found that urea, ammonium hydroxide and ammonium carbonate all induced root branching, but a variety of growth-substances tried were without effect

FORTHCOMING EVENTS

Saturday, May 19—Monday, May 21

ASSOCIATION OF SCIENTIFIC WORKERS (at the Beaver Hall, Garlick Hill, London, E C 4), Annual Council Meeting

Saturday, May 19

At 2-6 p.m.—Address by Prof P M S Blackett, F R S (president), and discussion on future policy for science

Sunday, May 20

10 a.m.—6 p.m.—Education policy Debate on a proposal to initiate a political fund Report on industrial work, negotiations with employers, etc Motions on the Trades Disputes Act and the National Health Service

Monday, May 21

10 a.m.—1 p.m. Relations with scientific organizations overseas

Tuesday, May 22

INSTITUTION OF ELECTRICAL ENGINEERS (RADIO SECTION) (at Savoy Place, Victoria Embankment, London, W C 2), at 5.30 p.m.—Discussion on "Non-Ferrous Contact Springs" (to be opened by Dr H G Taylor and Dr L B Hunt)

QUAKETT MICROSCOPICAL CLUB (at the Royal Society, Burlington House, Piccadilly, London, W 1), at 7.30 p.m.—Mr E R Newmarch "Fluid Mounting, with special reference to Narcotizing and Fixing Polyzoa"

Wednesday, May 23

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W C 2), at 1.45 p.m.—Mr Paul Adorjan "Wire Broadcasting" (Thomas Howard Lecture)

PHYSICAL SOCIETY (at the Royal Institution, Albemarle Street, London, W 1), at 4 p.m. Presentation of Duddell Medal to Dr F W Aston, F R S

Prof E N da C Andrade "The History and Future of the Physical Society" (Presidential Address) Annual General Meeting

Thursday, May 24

INSTITUTION OF ELECTRICAL ENGINEERS (at the Institution, Savoy Place, Victoria Embankment, London, W C 2), at 5.30 p.m.—Mr J C Bead "High-Voltage Steel-Tank Mercury-Arc Rectifier Equipments for Radio Transmitters", Mr P A T Bovan "The Application of High-Voltage Steel-Tank Mercury-Arc Rectifiers to Broadcast Transmitters"

ASSOCIATION FOR SCIENTIFIC PHOTOGRAPHY (at Caxton Hall, London, S W 1), at 7.0 p.m.—Annual General Meeting At 7.30 p.m. Mr S H Thorpe "Photography applied to Research in the Steel Industry"

Friday, May 25

ROYAL COLLEGE OF SURGEONS (at Lincoln's Inn Fields, London, W C 2), at 4 p.m.—Prof Arnold Sorby "Blindness in Great Britain: the Structure of the Blind Population and the Causes of Blindness"

ROYAL INSTITUTION (at 21 Albemarle Street, London, W 1), at 5 p.m.—Sir Geoffrey Taylor, F R S "The Internal Structure of Turbulent Fluid Flow"

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned

SENIOR TECHNICAL OFFICER in the War Department Power Plants (Mechanical) Branch, Military College of Science, School of Tank Technology, Chertsey, Surrey—Ministry of Labour and National Service, Central (T and S) Register, Room 5/17, Sardinia Street, London, W C 2 (quoting Reference No C 2558 A) (May 22)

LECTURER IN MECHANICAL and/or ELECTRICAL ENGINEERING SUBJECTS at the Technical College, Cardiff—Director of Education, (C Hall, Cardiff) (May 22)

LECTURER IN THE CERAMICS DEPARTMENT, North Staffordshire Technical College, Stoke-on-Trent—The Principal (May 26)

LECTURER IN ELECTRICAL ENGINEERING at Aston Technical College, Birmingham—Chief Education Officer, Birmingham Education Committee (May 28)

SENIOR LECTURER IN AERODYNAMICS at the Royal Aircraft Establishment Technical School, Farnborough—Ministry of Labour and National Service, Central (T and S) Register, Room 5/17, Sardinia Street, London, W C 2 (quoting Ref No C 2571 A) (May 28)

RESEARCH POMOLOGIST at the Department of Agriculture Horticulture, University of Bristol, at Long Ashton Research Station—The Secretary and Registrar, University, Bristol, 8 (May 31)

PROFESSOR OF AGRICULTURE AND DIRECTOR OF THE COLLEGE F at the University College of North Wales, Bangor—Acting Registrar (May 31)

PROFESSOR OF MATHEMATICS at the University College of North Wales, Bangor—The Acting Registrar (May 31)

LECTURER IN ANTHROPOLOGY with special reference to West African TUTOR IN COLONIAL WELFARE PROBLEMS, LECTURER IN ECONOMIC and LECTURER IN INTERNATIONAL RELATIONS at the London School of Economics and Political Science—The Acting Secretary, London School of Economics, The Hostel, Peterhouse, Cambridge (May 31)

AN ASSISTANT CHIEF ENGINEER (MECHANICAL) (Ref No C 2589 J) and an ASSISTANT CHIEF ENGINEER (CONSTRUCTION) (Ref No C 2590 XA) at the Tata Iron and Steel Co., Ltd, Jamshedpur, Ind Ministry of Labour and National Service, Central (T and S) Register Room 5/17, Sardinia Street, London, W C 2 (quoting appropriate reference number) (May 31)

LECTURER IN GEOGRAPHY at King's College, University of London The Secretary, King's College, Strand, London, W C 2 (June 1)

LECTURER IN ELECTRICAL ENGINEERING, with knowledge of MECHANICAL ENGINEERING, at the Ipswich School of Technology—The Education Officer, Education Department, 17 Tower Street, Ipswich (June 1)

DIRECTOR OF THE SCHOOL OF LIBRARIANSHIP, University of London—Academic Registrar, University of London, Richmond College, Richmond, Surrey (June 1)

PROFESSOR OF GEOGRAPHY at the London School of Economics Political Science—The Academic Registrar, University of London Richmond College, Richmond, Surrey (June 4)

LECTURER IN PHYSICS at Loughborough College, Leics—Registrar (June 7)

DEMONSTRATOR and also TECHNICIAN IN THE CHEMISTRY DEPARTMENT, Guy's Hospital Medical School, University of London—G S Gibson, F R S, Chemistry Department, Guy's Hospital Medical School, London Bridge, S E 1 (June 16)

TWO UNIVERSITY LECTURERS IN MATHEMATICS at Cambridge The Secretary of the Appointments Committee (Dr R Stoneley), 1 broke College, Cambridge (June 30)

DEMONSTRATOR IN METALLURGY in the University of Cambridge The Secretary of the Appointments Committee of the Faculty of Physics and Chemistry (Dr F B Kipping), University Chemistry Laboratory, Pembroke Street, Cambridge (July 2)

READER IN ANTHROPOLOGY at the London School of Economics and Political Science—The Academic Registrar, University of London Richmond College, Richmond, Surrey (July 9)

PROFESSOR OF BACTERIOLOGY at University College Hospital Medical School—The Academic Registrar, University of London Richmond College, Richmond, Surrey (Sept 24)

A LECTURER IN GEOGRAPHY and a LECTURER IN BIOLOGY at Hill Training College, London—Principal, at Sandy Mount, Croft Moor, Huddersfield

LECTURER IN BOTANY at Birkbeck College, University of London—Clerk, Birkbeck College, London, E C 4

LECTURER IN MATHEMATICS at Woolwich Polytechnic, London S E 18—The Secretary and Clerk to the Governors

RESEARCH ASSISTANT (female) with Biological or Zoological qualifications at the Christie Hospital and Holt Radium Institute, Withington Manchester 20—The General Superintendent

TEACHERS OF MATHEMATICS, CHEMISTRY, METALLURGY, MECHANICAL ENGINEERING at the County Secondary School and Cumbe Technical College, Worthington—The Principal

SENIOR ASSISTANT IN THE DEPARTMENT OF METALLURGY, LECTURERS IN THE DEPARTMENT OF ELECTRICAL ENGINEERING, LECTURER IN BUILDING SCIENCE, LECTURER IN PHARMACOLOGY SUBJECTS (temporary) at the Birmingham Central Technical College, Suffolk Street, Birmingham—The Principal

TELEVISION AFTER THE WAR

ONE of the most remarkable achievements in the application of science to the everyday life of the community was the development of television before the War. The first public service of high-definition television, in Great Britain or any other country, was inaugurated at the British Broadcasting Corporation's station at Alexandra Palace in November 1936. Prior to the closing down of the station for military reasons in September 1939, the television service had reached a high standard, the programme technique had made great progress, and the result was a service of considerable entertainment value. Some twenty thousand television receivers were in use by the general public, and although the service was confined to the London area, it is probable that several hundred thousand persons were more or less regular 'viewers' either in their own homes or elsewhere. These and many others have probably been wondering for some time past exactly what are the prospects of television after the War, and to what extent the lead which Britain established in this field nearly ten years ago will be maintained in the future. There has naturally been some cause for anxiety in this matter, since the United States had the advantage of more than two years of continued development on an almost peace-time basis after the outbreak of war in Europe, and even to-day there are in the United States a number of television transmitting stations in operation on an experimental or other basis.

Although for some years past the entire technical resources of Britain have been mobilized for the provision and operation of radio equipment required for the conduct of the War, a few members of the industry, Government establishments and the B.B.C. have been able to give some thought to matters concerning the future organization of a television service. For example, a paper entitled "A Survey of the Problem of Post-war Television" was read by Mr B. J. Edwards before the Radio Section of the Institution of Electrical Engineers last year, and the paper, with the extensive discussion which followed it, have recently been published in the *Journal of the Institution* (91, Part III, 163, December 1944). Technical discussions before the same Institution on matters affecting the improvement of television were also held in the previous year (*J. Inst. Elec. Eng.*, 90, III, 147 and 91, III, 11). More recently, Mr H. L. Kirke, of the B.B.C., has given a discourse on the subject before the Royal Institution, an abstract of this will be found on p. 621 of this issue of *Nature*.

In the meantime, the Television Committee, appointed in 1943 under the chairmanship of Lord Hankey, has completed its duties, and its report, issued a short time ago, provides a very careful and authoritative review of the whole subject.*

The Television Committee was charged with the duties of preparing plans for the reinstatement of the

* Report of the Television Committee Pp 26 (London H.M. Stationery Office, 1945) 6d net

television service of Great Britain and its extension to the larger centres of population, and of considering the provision to be made for research and development and the guidance to be given to manufacturers, with a view especially to the promotion of the export trade. The report opens with a reference to the first Television Committee under the chairmanship of the late Lord Selsdon, and to the installation of the Alexandra Palace station after the report of this committee (Cmd 4793) was published in 1935.

It is now generally recognized that past research work on television contributed very materially to the successful and rapid development of radiolocation, but the Committee finds that war research has produced little information and no discovery of a fundamental character bearing directly on television. War demands and activities have, however, greatly extended the technique of the radio engineer, and increased the number of skilled men and women who will eventually be available in all grades for the work of development, design and maintenance of television.

With these considerations in mind, the Committee's first and foremost recommendation, which is supported by the majority of the witnesses from whom it received information and advice, is that the pre-war system of television on the basis of 405-line definition should be restarted in London (Alexandra Palace) as soon as possible after the cessation of hostilities in Europe. An appendix to the report gives a description of this London Station and of the Maconi-E M I system used there, it is believed that the service could be restored to operation within nine to twelve months of the release of the requisite staff. Next, with the view of securing a full development of the television industry and making a larger section of the population television-minded, it is recommended that an extension of the existing system to the provinces should be planned, essentially for the dissemination of the same programmes over a larger area of the country. Thirdly, the Committee recommends that vigorous research work on a radically improved system of television should begin immediately staff can be made available, and that the objective in this case should be the cinema standard of definition of the order of 1,000 lines with, if practicable, the introduction of colour and stereoscopic effects. The scope of the extension of the existing system to provincial centres should be kept under review, so that any improvements, resulting from the research work suggested, may be introduced as early as possible to the public service.

Having stated in the above general manner the policy recommended by the Committee for the provision and development of a post-war service, the report then proceeds to a discussion of some details of the plans required to put these proposals into effect. It will be necessary to obtain agreement with the various interests concerned on the allocation of appropriate frequencies for television transmission both in the immediate and more distant future. Associated with this problem is that of electrical interference, which to a considerable extent hampered or restricted the successful reception of pre-war television programmes. As the potential sources of

such interference are likely to be far more numerous after the War, it is considered to be vital to the success of television that the Postmaster-General should be granted the necessary powers to enforce suppression of such interference.

On the question of research, two entirely different courses have been considered, neither of which is considered to be likely to lead to the most efficient and economical progress. It has been suggested that there should be complete unification of research effort of all interested firms in the formation of a research association, and alternatively, that the development of an improved system should be left to free competition between large firms, apart from research on certain fundamental problems on radio wave propagation, which would probably be undertaken in any event by Government institutions. In place of these suggestions, the Committee recommends that, while individual effort should receive all possible encouragement, television research should be co-ordinated, with the collaboration of all the interests concerned. It is understood that the Government research organizations of the Department of Scientific and Industrial Research would be prepared to assist the industry in any way possible in the development of television. The British Broadcasting Corporation will doubtless be able to assist considerably in co-ordinating effort in the development of an improved system, while the Post Office will assume responsibility for the outstanding problems of relaying programmes by cable and radio links. Since the ultimate aim of all interested parties is the establishment of the best television service, and as it is probable that only one transmitting system—as distinct from receiving apparatus—will be chosen for the new British service, the problem of patents becomes one of special difficulty. This problem appears to be essentially one for the industry, and it is recommended that the manufacturing firms should be encouraged to pool their television patents with the view of ensuring that they are made available for use as the national interest may demand.

The Committee gave special consideration to the item in its terms of reference concerned with the development of the export trade, an aspect of television to which the industry appears to be thoroughly alive. General agreement was found in the fact that the first step in this direction is to popularize television at home, since a flourishing home market in suitable receivers is an essential pre-requisite of an export trade. While the industry itself must be responsible for the development of such trade, it should keep a close watch on possibilities and prospects, and arrangements should be made for the Government to be advised of developments in the television system so that these may be brought to the notice of Dominion and foreign Governments. Partly in this connexion, the Committee has given much thought to the question of bringing the British television standards into line with the American pre-war standards based on 525 lines per picture. It is implicit in the recommendations already described to re-establish the London station on its previous basis of 405 lines that such a change is considered to

not worth while at the present time. It is urged, however, that the ideal of international standardization should be kept constantly in mind, not only for line and picture details, but also for the bands of frequencies of radio carrier waves allocated to television.

An important section of the Committee's advice is concerned with the organization and administration of the television service and with the financial arrangements involved therein. Before the War, the Minister responsible for television on behalf of the Government was the Postmaster-General. The question of future arrangements is part of the wider subject of the relations between the Government and

British Broadcasting Corporation, which is a matter outside the terms of reference of the present committee, it is suggested, however, that the Minister responsible to Parliament for sound broadcasting should also be responsible for television. In this way, it is considered desirable that the B B C should operate the television service, owing to its connexion with sound broadcasting. After making estimates of the cost of re-opening the television service and its extension to the provinces, it is recommended that domestic television viewers should be required to have a special licence at a fee of £1 a year. It is also suggested that a cinema television licence might be introduced in the future, and this might become an important source of revenue. The interests concerned have, however, estimated that except possibly in the case of isolated areas, they will not desire to embark on the use of television in cinemas until a new and improved system has been adopted. The report also refers to the possibility that an appreciable amount of revenue might be derived from the inauguration of sponsored television programmes with appropriate advertising charges paid for by commercial interests. It is recognized that this question raises wider issues than merely financial ones, and it is felt to be premature to come to a conclusion thereon at the present time. Much of the success of the development of television before the War was due to the activities of the Television Advisory Committee, which was set up in accordance with the recommendations of Lord Don's Committee. The present Committee endorses this procedure by recommending that the Minister responsible for broadcasting should appoint a corresponding committee to fulfil a similar purpose, any rate until the service is more or less stabilized. It is suggested that this advisory committee should include representatives of the Treasury, the General Post Office, the Department of Scientific and Industrial Research and the British Broadcasting Corporation, its function would be generally to advise the responsible Minister on questions of major policy on any problems arising from the development of television both at home and abroad.

Under the guidance of such a body, which would fully consider all phases of the report recently published and, where necessary, ensure that the recommendations are implemented in the most judicious and efficient manner, it can confidently be anticipated that television will develop on sound

lines in Britain and maintain the position and prestige which had been so well established some six years ago. There is no doubt that television has come to stay, and has already reached a stage that gives satisfactory results in the home. British science, engineering and industry, working in co-operation with the B B C on the lines suggested in the present report, can be trusted to produce an improved system which will contribute worthily to the progress of an art the significance of which for international understanding can even now scarcely be exaggerated.

THE MOTOR AREA OF THE BRAIN

The Precentral Motor Cortex

By Charles D. Aring, Percival Bailey, Gerhardt von Bonin, Paul C. Bucy, Charles Davison, Theodore C. Erickson, John F. Fulton, Marion Hines, Margaret A. Kennard, Paul M. Levin, Warren S. McCulloch, James L. O'Leary, Wilbur K. Smith, Sarah S. Tower, A. Earl Walker. Edited by Paul C. Bucy. (Illinois Monographs in the Medical Sciences, Vol. 4, Nos. 1-4.) Pp. xiv + 605. (Urbana, Ill.: University of Illinois Press, 1944.) 4.50 dollars.

THE opening pages of this book are a sharp reminder of the misfortunes of Europe. It is dedicated to Otfried Foerster, the great neuro-surgeon of Breslau, and the foreword by John Fulton recalls the work of Dusser de Barenne at Utrecht. Dusser de Barenne left Utrecht for Yale in 1930, and the main development of his new methods took place there. But to many members of the Physiological Society his name will recall their visit to Holland in 1925, where they saw Einthoven at Leyden with his string galvanometers, Dusser de Barenne, Zwaardemaker and de Kleijn at Utrecht, and Magnus with his team of neurologists in the old plague hospital of the town. They will remember the cheerful and almost overwhelming hospitality of their Dutch colleagues, the fine buildings and the prosperous countryside.

The precentral motor cortex certainly deserves a volume to itself, for most of our knowledge of the brain has been derived from its study. When Fritsch and Hitzig found in 1870 that electrical stimulation of this part of the cerebrum would produce localized movement of the limbs, an entirely new chapter of cerebral physiology was opened. It became possible to trace the pathways of conduction, to map the excitable areas in different animals, and to analyse the movements caused by stimulation. No other part of the brain surface could yield such a rich harvest, for in no other part would electrical stimulation give such obvious results. The maps have become more and more detailed, with the inclusion of the anthropoid apes and of man in the series, and the method now seems to be reaching the limit of its usefulness. Indirectly, however, there is no field of research on cerebral localization which is not derived from these early studies of the motor area.

Otfried Foerster was the first to make extensive use of electrical stimulation of the human brain in the course of neuro-surgical operations. Dusser de Barenne introduced the use of strychnine instead of the electric current to stimulate the cerebral nerve cells. He employed it originally in investigations of the sensory area, applying it locally to the cortex and

judging the results by the disturbance of sensation which it seemed to induce. The results were striking, but it was not until he began to record the electrical activity of the cortex that the full possibilities were evident. Strychnine is a convulsant drug which produces an explosive discharge of the nerve cells, and this gives rise to characteristic electrical activity wherever the axons of these cells are to be found in sufficient numbers. Thus the axons leading from any point on the cortex can be followed to their destination by applying strychnine to the point and finding what other regions give the large 'strychnine spikes' in an oscillograph record. We have therefore a new and very effective way of tracing the intricate pathways from cell group to cell group in the cerebral cortex as well as those between the cortex and other parts of the nervous system. In this volume the application of the method to the study of the pre-central area is described by Warren McCulloch, who has worked in close collaboration with Dusser de Barenne and is now the chief exponent of his ideas.

This is the most recent method of tracing cerebral connexions, but the study of the motor area has progressed on many other lines. To deal with them the editor has assembled a team of neurologists, each of whom is an expert in his or her field (for Sarah Tower, Marion Hines and Margaret Kennard have contributed some of the most interesting chapters). The structure, pathology, somatic and autonomic functions are all dealt with, and the editor describes the results of his own operations on the motor area in man.

The volume gives a clear survey of work which is rapidly filling in the blank spaces and giving fresh detail to the neurologist's picture of this part of the brain. It may be that the picture when completed will not be much more than an elaborate railway guide with all its maps and time-tables, and we may not be much nearer to an understanding of the way in which the rest of the brain makes use of its motor area. But this could be said of most neurological research nowadays. It does not make the picture less necessary, and it does not lessen our gratitude to the editor and to the University of Illinois for such a valuable monograph.

E D ADRIAN

RUSSIAN APPRECIATION OF THE NEWTON TRICENTENARY

Isaac Newton 1643-1727

The Third Centenary of his Birthday. Symposium edited by S I Wawilow. Pp 437. (Moscow and Leningrad Academy of Sciences of the USSR, 1943) 25 roubles.

THIS book, containing eighteen articles, each concerned with a different aspect of Newton's work or influence, is an important contribution to 'Newtoniana'. Being written in Russian, it is not easily accessible to English readers. The nature of these articles and their total bulk make it impossible in a review to do more than list and classify them, and to indicate some of the more interesting or outstanding features.

First, however, the title "Isaac Newton 1643-1727" calls for comment. The date 1643 is based on the new or Gregorian Calendar which was introduced into England in 1752, twenty-five years after New-

ton's death. According to the old or Julian Calendar Newton was born on December 25, 1642.

The collection is edited by S I Wawilow, a great authority on Newton in the U S S R. He has recently published a book on Newton and translated "Optics" into Russian. A characteristic common to all the articles in the symposium is the profound admiration for and understanding of Newton's work shown by the contributors. But the articles are confined to eulogisms or to the giving of information. Each is a study in criticism and interpretation.

Some of the articles, particularly those dealing with the progress of Newtonian philosophy in Russia, with Newton's influence on the development of European thought, would be of a particular interest to an English reader. Such is the article by T Kravetz, in which he traces the progress of Newton's views in Russia. In the minutes of a meeting of the newly founded Russian Academy of Sciences held on November 13, 1725 (the first to be recorded) an account of a disputation held about Newton's work on the figure of the earth. During the following year there were public lectures devoted to the position of the natural philosophy of Newton. From this date Newtonian mathematical methods were taken over and developed by such outstanding mathematicians as L Euler and the brothers D'Alembert and Nicholas Bernoulli, at that time attached to the Russian Academy. At a slightly later date the outstanding Russian man of science, M V Lomonosov (1711-65), was influenced in some degree by Newton but the greatest development took place in the nineteenth century when Newton's views passed into the main stream of European scientific thought. It is interesting to note that D I Mendeleev was greatly influenced by Newton and even called his hypothetical proto-element 'newtonium'. A new phase of Newtonian study began during the present century, especially after the appearance of an excellent Russian translation of the "Principia" by A Krylov in 1916 and "Optics" by S I Wawilow in 1927. The account of the progress of Newtonian studies in Russia is continued in the article by T Ramov, in which the author deals mainly with certain aspects of scientific work of M V Lomonosov, D I Mendeleev and A N Krylov, and traces the development of the mechanistic interpretation of natural phenomena. The influence of Newtonian philosophy on French thought, and especially the conflict between the Cartesians and the Newtonians, is very ably discussed by A D Lublinskaja. To take a wider view, A M Deborin traces the influence of Newtonian ideas on the development of European philosophy and culture in relation to the changing social background. The important position of Newton as the transformer of the Newtonian structural scheme into a genetic scheme is emphasized, and is linked up with the evolutionary idea which became so prominent in the nineteenth century.

The articles dealing with the scientific aspect of Newton's work are probably the most important in this symposium, but only a list of their titles can be given in this review. They are as follows: A Krylov, Sir Isaac Newton and his role in science; S I Wawilow, ether, light and matter in Newtonian physics; G G Shussarev, Newton's works on geometrical optics; I A Khvostikov, Newton and the development of the theory of refraction of light in the atmosphere; N I Idelson, the law of universal gravitation and the theory of the motion of the moon; L N Sretensky, Newton's theory of tides and

ure of the earth, A D Dubiago, the comets and their significance in the general system of Newton's "principia". The same, unfortunately, must be done with the mathematical articles, which are as follows:

N Luzin, Newton's theory of limits, S Y. Luria, Newton's forerunners in the philosophy of the infinitesimals, N G. Tschebotarow, Newton's polygon and its role in the present development of mathematics, M V. Kirpichev, Newton and the theory of similarity.

Finally, there are three articles, which cannot be assimilated with the others. One, by P M Dulsky, on the existing portraits of Newton. Another, by Y Luria, on Newton as an historian of antiquity, a most interesting article giving a detailed account of Newton's work on chronology and criticism of the aptitudes, and discussing the importance of this work in the development of historical science. Finally, there is a very vivid account by E Ch Skrijnskaia of Newton's life and work in Cambridge. The author records the influence of Barrow's teaching on the development of Newton's thought, and after discussing the Cambridge environment, raises the question: How much did Cambridge contribute to Newton's development? This question, she suggests, could really be inverted and put this way: How much did Newton contribute to the development of Cambridge? "The answer is self-evident. Newton brought to the University the glory of being the latest scientific centre, Newton raised the University to an unprecedented height of scientific achievement by the mere fact that he was there—a student, fellow of one of its Colleges and its professor. Really, it was from this Cambridge retreat that the world received the greatest achievement of human thought, it was here indeed that in a modest room of study was written the 'Mathematical Principles of Natural Philosophy'." The words of its author flared with such brilliant light that even now, two and a half centuries after Newton was associated with Cambridge, this University has neither lost nor diminished its brilliant reputation—the source of great and progressive ideas in natural science and mathematics."

S I TOMKEIEFF

A THEORY OF TELEPATHY

Telepathy

Outline of its Facts, Theory and Implications
Whately Carington. Pp xiii+176 (London: Methuen and Co, Ltd, 1945) 12s. 6d net

THE timely appearance of this volume is an indication that the more serious among experimental psychical researchers are beginning to feel the necessity of fitting the facts they have so far amassed on telepathy into a theory which may at least be able of stimulating further thought, if not of explaining some of the facts which seem to them indisputable.

Mr Whately Carington sets out by briefly summarizing the results of earlier experiments, and shows how development has proceeded in a direction in which statistical analysis has played an increasingly important part. He then passes on to a consideration of the objections and resistances which have been encountered, although in this section he seems rather too much inclined to attribute the hesitancy of scientific men to accept the findings of themselves and others to "a fear of finding something

they cannot explain away" (p 42), or to a haunting fear that the facts, if confirmed, might "weaken the status of Causality and Law" (p 44).

It is in Part 2 of his book, however, that the author embarks on his theoretical treatment, which must prove of considerable interest both to psychologists and philosophers. Briefly stated, Mr Carington's view of the mind seems to approach that held by Bertrand Russell, and lies in the direction of a theory that the 'mind' consists solely of *sensa* and images, which are "real entities existing in their own right". These constituents he calls 'psychons', and each mind consists of clusters of these psychons gathered around certain nuclei, the moods, etc., within each individual mind being considered as smaller and weaker clusters grouped around other nuclei. Thus in Mr Carington's view the mind is really a kind of system of psychons held together by associative linkages, and it is in this idea of *association* that he sees a fruitful theory developing, which, he thinks, will go far to explain such phenomena as telepathy, extra-sensory perception, and so forth.

The basic principles of this law of association are easy to grasp and, as Mr Carington says, have the merit of simplicity as well as of close connexions with psychological processes already fairly well known. Thus if two ideas, *A* and *B*, are presented together, or in close succession, to any mind and later one is re-presented, then the other is more likely to accompany or follow it than if they had not been so previously presented. In telepathy, an idea *A* may be associated with an idea *K* in the mind of the experimenter or agent; then, if *K* is presented to the percipient's mind, *A* is more likely to come into it than it would be if *A* had not been associated with *K* in the mind of the agent.

In his account of his theory, Mr Carington shows how many of the facts become more easily explicable if it be used, and how later research may amplify and modify his basic conception of it. Nevertheless, he does not hesitate to discuss such problems as survival in the light of his ideas regarding the stability of the psychon systems under post-mortem conditions. Recognizing that such systems might be imagined as persisting after the death of the body, he sees very clearly that the problem of their stability is crucial. What guarantee, he asks, have we that they will stick together and not disintegrate when the influx of sensory stimuli ceases? The question of the breakability or otherwise of the links in each psychon system must determine the survival or disintegration of each personality after death. To suppose such breakability to be a fact would, Mr Carington insists, be a conception "much too material and quite illegitimate", and, moreover, contrary to every indication. Yet this was precisely the suggestion put forward forty-one years ago by Dr Walter Leaf when reviewing Mr W H Myers' great work on "Human Personality". Much of the evidence from trance mediumship suggests it. Dr Leaf postulated the existence of surviving 'memory groups' undergoing a slow process of dissolution, and indeed he declares that, judging from the history of the various mediumistic trance personalities, their mental attitude "seems distinctly to point to the cluster of memories disintegrating—full of the gaps and vaguenesses which we should expect to find as the forerunners of ultimate dissolution."

However this may be, the present contribution to the theory, as apart from mere presentation of experimental data, is to be welcomed, and doubtless will

not only excite much controversy among those at present in the field, but also stimulate others to take a more serious view of what is one of the most exciting and intriguing problems involving, as it does, psychological, philosophical and religious speculation

E J DINGWALL

AMERICA'S MINORITY PROBLEM

The Navaho Door

An Introduction to Navaho Life By Alexander H. Leighton and Dorothea C. Leighton Pp xviii+149 +36 plates (Cambridge, Mass. Harvard University Press, London Oxford University Press, 1944) 22s. 6d net

DRS A H and D C. LEIGHTON are deeply concerned that the United States may be truly prepared to play the great part which she inevitably must in building international peace, and they see clearly that this preparation must begin at home "We cannot hope to be on proper terms with Russians, Argentinians, Peruvians, British and Chinese, if we are unable to understand the cultural groups who are much more easily within the range of our comprehension." By a happy chance, the Navaho Indians, whose reservation lies in the States of Arizona, Utah and New Mexico, came to their attention, and they decided to live and work among them, and try to see things through Navaho eyes. This book is a measure of their success, and is a notable contribution to the sympathetic understanding and fair treatment of the Indian. "It was obvious that we could not study all the world, but we could study the Navahos," and they did so in the hope that the principles which they learnt might have an application to a much wider circle. It is natural, in a book written by physicians, that much space should be devoted to medicine, but this, not less than the remainder of the book, will be of value to the anthropologist and of interest to the general reader.

Owing to the accidents of history, there came a time in the nineteenth century when the Navahos were outcasts and every man's hand was against them. Finally they came to terms with the U.S. Government, which established them on their reservation and put them under the enlightened administration of the Indian Service, but even then their troubles were not ended. There are always white men who are ready to take the Indian's land and exploit his labour, excusing themselves on some fair-sounding pretext, and the Government has not consistently set its face against political pressure designed to this end. The danger is not past, and to counteract it is one of the objects of the book.

The most illuminating parts of the chapters on medical treatment and education are the specimen speech on health and the examples of interviews with Indians suffering from various diseases, which give an insight into the way in which the medical man must approach these matters if he is to get any response from his patients. Great emphasis is laid throughout on the help which can be got from native religion and the methods of treatment which are so intimately bound up with it. One chapter is devoted to the life-stories of three Navahos, told as nearly as possible in their own words. The remaining chapters, on history, environment and society, religion, the Indian Service, and future prospects, are informative and sufficient to give a background to the main pur-

pose of the book, but anthropologists must not expect full and detailed descriptions of customs and material culture like, for example, the works of Leslie White the Pueblos. The production of the book leaves nothing to be desired, the illustrations are superb.

In spite of the poverty of much of the land on the reservation and the uncertainty of the harvests, the Navaho population has increased threefold under the Indian Service. The head of this service, the Commissioner of Indian Affairs, at whose request the book was written, pays handsome tribute in a foreword to the practical help which its administrators have already received from the Leightons' studies, and workers in other fields will doubtless derive a benefit from them.

G H S BUSHNELL

SOME TICKS OF NORTH AND CENTRAL AMERICA

The Argasidae of North America, Central America and Cuba

By R. A. Cooley and Glen M. Kohls (American Midland Naturalist, Monograph No 1) Pp v+141. (Notre Dame, Ind. American Midland Naturalist, University of Notre Dame, 1944) 2 dollars

THE Argasidae are an important family of ticks and several of their species are of medical and veterinary significance. In so far as the North American kinds are concerned, five species *Ornithodoros* are proved carriers of the spirochaetae of relapsing fever. Rocky Mountain spotted fever has been experimentally transmitted by *Ornithodoros parkeri* and *O. hermsi*. *Argas persicus* is a widespread notorious pest of poultry; the birds may become weakened owing to loss of blood and, when large numbers of ticks are involved, the effects often cause death of the hosts. This tick may also be the carrier of avian spirochaetosis, at least in Texas. The spinose ear tick of cattle, *Otobius megnani*, is a serious enemy of young animals in particular, causing much irritation and loss of condition. This species, however, has not been shown to be concerned with the transmission of any specific disease organisms.

Messrs Cooley and Kohls' monograph is a competent taxonomic study of the species affecting the area under consideration. The classification of ticks beset with difficulties and not the smallest of them, as the authors point out, the lack of adequate characters upon which the genera are to be founded. So far, no genera have been synonymized, but with the increasing numbers of new species that are being discovered it has become more and more difficult to separate the genus *Argas* from *Ornithodoros*. This difficulty has resulted in the authors meeting it by modifying the diagnoses in the two genera just quoted. Host specificity varies a good deal among different species and a surprising number of North American kinds have been found on bats. The authors recognize four genera of Argasidae, and include at least twenty-five North American species. Two of these species belong to the genus *Argas*. *Ornithodoros* includes nineteen species and there are two species each in *Otobius* and in *Antricola*.

Wherever possible, descriptions are given of the adult, nymph and larva in each case. A classified list of hosts is given together with a glossary of the terms used and a bibliography. The work is illustrated by fourteen plates and fifty-seven text-figures (including maps).

TELEVISION—PAST AND FUTURE

AS we are able to look forward to conditions of peace in Europe, it is natural for our thoughts to turn towards the resumption of many of the amenities of civilized life, which has been so seriously restricted during the War. Among these amenities is the reception of television programmes for instructional and entertainment purposes, a service which was provided by the London Television Station over a limited area of Great Britain for a year or two preceding the outbreak of war. In view of the widespread application of radio technique to military purposes, and the outstanding advances made in various directions during the past five years, it is natural to inquire in what way and to what extent radio broadcasting and television will benefit when this technique and the personnel trained in its use are directed to the exploitation of these peace-time pursuits. It is therefore relevant to refer in some detail to an address entitled "Some Aspects of Pre-War and Post-War Television" given to the Royal Institution on March 2 by Mr H. L. Kirke, head of the Research Department of the British Broadcasting Corporation.

This address surveyed the general principles of modern television practice and the technical features and requirements, Mr Kirke also directed attention to the various problems which must be solved before certain developments and improvements, which have been foreshadowed in some quarters, can be incorporated in a reliable service for the public needs.

Picture Scanning

Whatever system is employed for the transmission of a television picture, basic necessities are the analysis of the picture or scene at the transmitting end, and its synthesis at the receiving end. Thus the picture or scene is broken down into a number of small elements, so that the degree of light or shade, or even colour, of each element can be transmitted independently and reassembled in the correct order at the receiving end. The degree of distortion of the picture, or its complement the definition, will depend upon the number of elements into which the picture is divided, and the size of the resultant received picture as it appears to the eye of the viewer.

The usual arrangement for scanning a picture is to divide it in effect into a number of horizontal lines, each of which is scanned or seen by the television apparatus, element by element, usually from left to right. The scanning of a picture in this way can be visualized by imagining it to be divided into a number of strips, the right-hand end of one strip being joined to the left-hand end of the strip below to form one continuous strip. This strip can now be considered as passing a slit through which elements of the picture are exposed to a photo-electric cell as the strip passes by. The current output from the photo-electric cell at any instant is a function of the average amount of light falling upon the cell at that instant, so that the definition in the horizontal plane depends upon the size of slit or aperture, while the definition in the vertical plane is a function of the line width and therefore of the number of lines. When the scanning is done with a square or round aperture, the definitions in the vertical and horizontal directions are the same, and this is the usual arrangement. For the transmission of moving pictures, the whole field of view must be repeatedly scanned at a rate exceeding

twenty-five pictures per second, in order that the eye shall not be conscious of flicker, a condition corresponding to practice in cinematography.

The sharpness or definition of a picture depends upon the number of elements into which it is divided for scanning purposes, and the radio-frequency band width occupied by the transmission of a picture depends upon the number of picture elements per second. The London Television Station at Alexandra Palace, before the War, transmitted pictures divided into 405 lines at the rate of twenty-five pictures per second, and these occupied a radio-frequency channel of 5 megacycles per second wide. By the use of a device known as interlaced scanning, it is possible to transmit a 405-line picture with only twenty-five complete pictures per second in such a manner that the flicker corresponds to fifty pictures per second. Interlaced scanning is achieved by scanning alternate lines of a picture in sequence followed by the scanning of the remaining intermediate lines. The repetition rate or flicker frequency is therefore twice the actual number of complete pictures per second. Thus alternate 'frames', as they are called in Britain, consist of 202½ lines each, while a complete picture of two frames comprises 405 lines. Interlace ratios other than two are possible but not usual in black and white television.

Electron Cameras

Although mechanical scanning systems have been developed and may still have possibilities, the more usual method makes use of a beam of electrons for the scanning process. The picture or scene to be transmitted is focused on a plate which comprises a mosaic of minute photo-electric cells, each of which acquires a positive charge to an extent depending upon the amount of light falling upon it. A beam of electrons is caused to traverse this mosaic in the scanning process, and at every point the current in the beam is proportional to the amount of light falling upon the corresponding photo-electric element. The resulting electric impulses are used to modulate the radio-frequency carrier wave of the television transmitter. The electron camera tube, particular versions of which are known as the 'emicon' in Britain, and the 'iconoscope' in the United States, is thus the link that converts the visual picture into electric signalling impulses. There have been a number of developments in electron devices and electron optics both in Britain and in the United States during and before the War which will undoubtedly be of considerable value in the further development of television camera tubes, and it is to be hoped that the considerable development of miniature components will enable the size of mobile television cameras to be reduced, as well as the size of apparatus for use in connexion with outside broadcasts.

Reception

At the receiving end the impulsive modulation is extracted from the incoming carrier wave, and used to vary in some way the intensity of light falling upon the viewing screen. The most widely used method of display before the War was the cathode ray tube, and it is probable that for a considerable time this will prove to be the cheapest and most popular form for home-viewing. The amount of development and the knowledge which has become available during the War will undoubtedly be of assistance in the improvement of the performance of cathode ray tubes, and

mass production methods should be effective in reducing the cost

The main limitation of the cathode ray tubes is the size of pictures which can be obtained. Pictures ranging from 5 in. $\times$ 4 in. to 10 in. $\times$ 8 in. were normally obtainable in commercial receivers, the former on cheaper sets and the latter on the more expensive sets. Even larger tubes have been made and used, and it is of interest to note that one firm in the United States has advertised that cathode ray tubes suitable for pictures nearly double that size will be available after the War. Whether these will be a commercial proposition remains to be seen. For large-screen operation a number of methods have been used. Most of these employ some form of small cathode ray tube with high intensity beam and a fluorescent screen from which the picture is projected on to a larger screen. Such devices have the disadvantage of being more costly and require very high voltages for their operation.

Programme Distribution

Now, it has already been explained that the radio-frequency band-width required for an effective television transmission is about ± 2.5 Mc/s., as compared with ± 10 or 15 kc/s. for good-quality sound broadcasting. To transmit the larger band required for a medium definition television system necessitates the use of a carrier frequency in the neighbourhood of 50 Mc/s., corresponding to a wave-length of 6 metres. The use of such a short wave-length restricts the range of reliable reception to some 30–50 miles, depending upon the height of transmitter and receiver and the existence of intervening hills, trees and buildings. With such a limitation on the range of transmission, it is clearly necessary to have several transmitting stations if the programmes are to be received in various parts of Britain.

The problem of communicating programmes from one station to another has received considerable attention, since the use of ordinary telephone cables to transmit the wide band of frequencies required is not very practicable. Special co-axial cables have been developed for this purpose, and preliminary work has also taken place on the use of radio links for point-to-point transmission. In each case, however, it is necessary to have amplifiers or repeater stations at five to thirty miles apart, so that the problem of relaying programmes over a distance of four hundred miles, such as from London to Glasgow, is quite a formidable one. Both cable and radio link methods had, however, been in successful use in Great Britain before the War, for supplying outside broadcast television features from a mobile transmitter developed by the B.B.C.

Future Developments

There is no doubt that a high-definition television system can be developed, and it would be possible to provide a service for the whole of Great Britain by such a system. Whether this could in fact be done is mainly an economic question. The cost of television programmes is many times that of sound programmes. The cost of television transmission apparatus is considerably greater than that for sound. The number and cost of technical, operational and programme staff is also considerably greater. The cost of distribution, whether by line or radio, will also be greater, and last but by no means least, the cost of the receiver is perhaps one of the most important factors.

Higher Definition

Mr Kirke then discussed the question of the definition that is satisfactory for a television service, particularly in connexion with the possible future increase in size of picture for home-viewing. The present American system uses 525 lines and 60 frames per second, but the resulting increase in band width is accommodated in about the same frequency channel of 4–5 Mc/s. by the use of asymmetric side-band transmission. It is doubtful, however, if it is worth while considering an alteration in the British system unless a change is made to 600, or even 800 lines with a corresponding increase in horizontal definition. In any event, much experimental development work is required, and it cannot be expected that any new system can be made available as a public service for several years after the end of the War.

One aspect of the subject that may settle the future trend of development is that of the size of picture required for normal home-viewing. At present this size is limited to 10 in. $\times$ 8 in., but it seems reasonable to anticipate the desirability of increasing this to 20 in. $\times$ 16 in. For the same viewing distance this will involve an increase in the definition in both the vertical and horizontal directions, and the resulting increase in scanning speed will require a band-width four times as great as at present. The carrier frequency will have to be correspondingly increased to at least 200 Mc/s., a wave-length of one and a half metres or less. The propagation characteristics of such short wave-lengths have certain disadvantages from a general reception point of view: the effect of ground contours and the shadows of hills and trees are more marked, and interference effect by waves reflected from buildings and other objects are more severe. Also, in general, the sensitivity of receivers would be less and the cost probably greater, although by development and mass production this cost might be reduced.

Colour

Demonstrations have already been given in Great Britain and in the United States of the possibilities of transmitting pictures in colour, which requires the use of two or more basic colours. At the transmitter filters can be used to separate the colours. In a mechanical system, as used in the United States, a rotating set of colour filters permits the projection of the various colour elements of the scene in turn on one photo-electric screen. The pictures contain the different colour elements are each scanned, and in some cases there is interlacing of the different colours. At the receiving end a similar rotating colour disk is used in conjunction with a cathode ray tube. In the electronic system demonstrated by Mr J. L. Baird in Great Britain, a two-colour and a three-colour process have been used experimentally. In effect, a separate screen is used for each colour, each screen being scanned by a separate electron beam. In colour television the total number of pictures transmitted per second must be increased as each colour requires a separate scan, and the increase in number of pictures per second requires a proportional increase in band-width. If the practical limit is the band width employed, it is necessary to compare the advantages of colour with the disadvantages of low definition.

There is no doubt that colour does give a considerable improvement to the picture. It appears to add another dimension, and provided a certain standard of definition is achieved in any event, then colour is a

great advantage. This is the experience of those who have experimented with colour photography, and it is certainly true of the cinema, although there are still many who say they prefer black and white.

If it be assumed that for a three-colour system the total number of pictures per second is doubled instead of trebled, then double the band-width is necessary. If the band width is 10 Mc./s., corresponding with 800 lines for monochrome, then a colour picture could be produced having 565 lines approximately; and a decision as to which was the better would be difficult, for a 565-line picture with colour would give an agreeable degree of definition and a pleasing result.

This point was demonstrated by Mr. Kirke by displaying two still pictures obtained in the United States about a year ago and taken with a mechanical colour switching system using 375 lines and 120 frames per second, the whole picture being accommodated in the standard American band-width of 4 Mc./s. The 375 lines in colour therefore correspond with 525 lines in monochrome: the pictures show that the apparent definition is rather surprising, and the compensating effect of colour is quite noticeable.

FORMATIVE EFFECTS OF ENVIRONMENTAL FACTORS AS EXEMPLIFIED IN THE DEVELOPMENT OF THE ONION PLANT

By DR. O. V. S. HEATH

Research Institute of Plant Physiology, Imperial College of Science and Technology, S.W.7

DURING the last two decades, discoveries of great importance have been made in the field of plant morphogenesis, and the predominant part played by the external factors of day-length and temperature has been established. Applications of this knowledge to the control of plant growth in agricultural and horticultural practice have led to important results, for example, in the forcing of bulbs (Blaauw, Van Slogteren and their associates^{1,2}) and the development of vernalization as a practical technique in the U.S.S.R.^{3,4,5}. In both these cases temperature effects are concerned; with regard to the length of day effects ('photoperiodism') the ample empirical knowledge we owe to Garner and Allard and subsequent investigators⁶ has so far yielded fewer practical results than might have been anticipated. The work dealt with in this article has brought to a focus these lines of research in an attempt to elucidate the behaviour of the onion plant.

The physiological investigation of the onion plant in this Institute began five years ago with the primary object of discovering the causes of 'bolting' (flowering) in onions grown from sets and the most satisfactory methods of control. As the work has developed, investigations on the mode of production, storage and use of onion sets have been carried out. The practical recommendations arising from this work are being dealt with elsewhere; the present account is concerned with the physiological effects of the factors of day-length and temperature, and their interactions, in controlling the developmental morphology of the onion plant—especially the processes of bulb formation, and flower initiation and development.

Onions are grown in practice from seed sown in the open, from transplanted seedlings, or from sets.

The latter are small bulbs, produced from seed in one season, stored dry through the winter and planted out in a second season to give a usable crop of large onions. Before the War, considerable quantities were imported, mainly from southern Europe. Their chief disadvantage is their marked tendency to bolt; the bulb produced is then generally small and of little value. In this work, therefore, the practical interest centres on preventing flowering, rather than hastening it as, for example, in vernalization. Bolting may be prevented in a number of ways, but there is little doubt that the most practical method lies in the use of suitable varieties^{7,8} and sets of suitable size^{7,8,9}. Selection of low-bolting strains has been carried out⁸ and re-selection work is being continued.

To provide a background for discussion, a brief description will first be given of the normal life-history of an onion plant, covering the whole growth and development from seed to mature harvested bulb, through two growing seasons and the intervening storage period; some of the experimental results will be intercalated as seems appropriate. Except where other references are given, the whole account is based on our own observations; but the development of the seedling (before bulb development) has also been described by Hoffman¹⁰ and that of the flower by Jones and Emsweller¹¹.

Development from Seed to Set

At germination of the seed the cylindrical cotyledon emerges, and through a pore near the bottom the first foliage leaf later protrudes. Each foliage leaf in turn emerges through a similar pore in its predecessor; the pore thus marks in each leaf the junction of the cylindrical leaf 'blade' and the cylindrical sheathing leaf-base. During development, the first formed portion of the leaf initial gives rise to a pointed structure, the embryonic leaf-blade. This expands both longitudinally and centripetally, over-arching the axis; at the same time the embryonic leaf-base extends round the growing point and completely surrounds it at a very early stage. The pore is thus left on the side of the axis opposite the tip of the leaf blade, and as the phyllotaxy is alternate, is thus in the correct position for the emergence through it of the next leaf in succession (Fig. 1). The leaf blade is at first solid, and only becomes hollow after emergence by the formation of a lysigenous cavity.

Before the onset of bulbing, new leaves emerge about once a fortnight, at ordinary summer temperatures, and there are generally three unemerged leaf initials to be seen at the growing point on dissection (Fig. 1). Under short-day conditions (less than about twelve hours) the plant can apparently continue growing and producing new leaves indefinitely in this way without bulb formation. The older leaves die off; the pseudo-stem or neck, formed of thin concentric leaf-bases enclosing a practically solid core of growing leaf-blade, becomes gradually thicker and longer; the short basal stem tends to rot away below but grows gradually at the upper end, where new adventitious roots emerge. After a time (eighteen months of artificially shortened days in one experiment) an inflorescence emerges; further leaf production is then carried on by an axillary bud: this mode of growth without bulb formation has continued for more than three years in the experiment cited.

Under natural conditions, however, the day-length ultimately attains a critical value at which a bulb begins to form; that this is a response to the

Fig. 1. LONGITUDINAL MEDIAN SECTION OF A 4-LEAVED ONION SEEDLING BEFORE BULB DEVELOPMENT. $\times 12$. LEAF NUMBERS: 1 TO 4, EMERGED LEAVES (4b1., BLADE; 4s., SHEATH); 5 TO 7, UNEMERGED LEAF INITIALS; r.i., ROOT INITIALS.

stimulus of long days is well established^{7,12,13,14,15}. The critical day-length varies for different strains of onion between about twelve hours and sixteen hours¹³ at ordinary temperatures. The effect of temperature on the photoperiodic requirements of seedlings is similar to that described below for plants grown from sets. With the onset of bulbing the sheathing bases of one or more of the *innermost of the emerged leaves* begin to swell, and this is either accompanied or followed by the swelling of the sheaths of usually three of the *outermost unemerged leaf initials*. This swelling occurs by increase in cell size and development of intercellular spaces, and without cell division.

When these unemerged initials swell to form bulb-scales they apparently suffer some irreversible change, for they lose the capacity ever to develop a leaf-blade, and this also applies to one or two of the adjacent unswollen initials. Furthermore, it has been found that when definite bulb development occurs, the emergence of further leaves normally ceases, immediately or soon according to the temperature^{9,14}. This observation has proved of the greatest value in accounting for the behaviour of the onion plant under various conditions^{14,16}.

Although no more leaves emerge after onset of bulbing the production of leaf initials at the growing-point goes on very rapidly until there are about nine unemerged leaves, of which the outermost 2-4 are swollen (Fig. 2). Some 4-6 of the unswollen leaf initials are available to produce foliage leaves in the next growing season; this number varies but little with set size¹⁷ and hence the higher yields obtained with large sets, in the absence of bolting^{7,8}, is due to large size of parts rather than to a greater number of leaf initials ready for emergence¹⁷.

In this condition the neck of the onion plant collapses, the leaf blades falling over on to the ground while several of them are still green and turgid. This collapse can occur with abundant soil moisture, though hastened by drought, and is due to the cessation of emergence of new leaves at bulbing. When the blade of the last leaf has fully emerged,

the neck no longer has a solid core (as in Fig. 1) and thus becomes a thin-walled hollow tube formed of concentric leaf-bases. This tube readily buckles under the weight of the green leaf-blades, especially in wind or drought¹⁶.

Following the collapse of the neck the leaves die and the bulb enters upon a dormant period, which can also occur with plentiful soil moisture; if the bulb has been kept small by late sowing and close spacing it now constitutes an onion set, which is normally lifted and stored dry through the winter.

The processes of bulb development and ripening normally follow the course outlined above, once bulbing has begun. But if plants that have recently begun to form bulbs are again subjected to short days, although some individuals complete their bulb development and ripen satisfactorily, in others the process of bulbing is arrested and the emergence of new leaves begins again, some of these leaves then showing transitional forms between true foliage leaves and bulb scales; lowering the temperature may have similar effect. There thus appears to be a critical stage in bulbing beyond which the process becomes irreversible. The practical interest lies in the similar reversal of the bulbing process which sometimes occurs, under field conditions during August or September, in onion plants which have bulbed late owing to very late sowing or low temperature. The longer the harvest of such plants is delayed the worse they become.

Development during the Dormant Period

With ripening, activity at the growing point almost ceases; during storage at ordinary temperatures only one to two more leaf initials are formed, and these mainly during the latter part of the winter¹⁷. Then, in March or April, the central axis bearing the terminal growing-point begins to elongate, as the first stage in the development of a scape. At the same time a spathe develops, and a lateral bud appears in the axil of the last leaf initial (Fig. 3). This stage of inflorescence development seems to be reached rapidly, but no further development occurs until after the set has been planted out.

Inflorescence initiation only occurs in bulbs above a certain size which varies with the variety of onion and is of the order of 2 gm. weight or 1½ cm. diameter. Inflorescence initials have only been found where a

total of at least thirteen leaf initials has been formed at the growing point¹⁷ and this may represent the stage of 'ripeness to flower'¹⁸. The mode of operation of this 'size effect' is under investigation.

When inflorescence initiation occurs in a bulb as described above, the plant has necessarily been exposed to long days to enable a bulb to form. The flowering of plants kept in short days throughout, described earlier, shows that at no stage of ontogeny are long days (> 12 hours) essential either for initiation or emergence of inflorescences. Short days ($< 16\frac{1}{2}$ hours) have similarly been found to be inessential.

Development from Set to Mature Onion

When the set is planted out, the eight or nine swollen leaf initials begin to elongate, all except the outermost one or two having leaf-blades; the swollen scales shrivel and later rot away. During a period of about a month at ordinary temperatures three or four leaf-blades emerge in rapid succession. Hereafter the leaves emerge in serial order about once a fortnight. In due course, in the absence of bulbing and if the set was large enough to have formed an inflorescence initial, the inflorescence merges from the sheathing base of the last leaf.

Under long-day conditions, however, renewed bulb development occurs. The critical day-length for plants grown from sets is almost certainly lower than for seedlings¹⁴, which perhaps accounts for the earlier crops from sets¹⁹. For a given day-length, bulbing is accelerated by high temperature and greatly delayed or prevented by low temperature^{7,14,15}; thus at lower temperatures longer days are needed. There appears to be a minimum time-lag of about three weeks between the first application of the long-day stimulus and the first external appearance of bulb development ($21-27^{\circ}\text{C}$. and $16\frac{1}{2}$ hours).

If conditions are such as to produce early and rapid bulbing, inflorescence emergence is suppressed¹⁷. This appears to be a consequence of the stimulus to bulb formation, for at temperatures low enough to prevent or greatly delay bulbing, long days actually accelerate inflorescence emergence¹⁵. The acceleration is thought to be brought about mainly by a great increase in the rate of scape elongation, associated with more rapid emergence of the surrounding leaves; inflorescence initiation is apparently independent of day-length¹⁵. This effect of long days on elongation of the scape resembles their effect on the 'shooting'

of spring cereals²⁰. It would appear that long days always promote cell extension in the onion plant. At moderate and high temperatures long days promote radial extension (bulbing) and limit longitudinal extension (emergence of new leaves and inflorescences); at lower temperatures such longitudinal extension is enhanced and radial extension inhibited.

Since long days combined with high temperatures prevent inflorescence emergence, late planting of sets in the field should reduce bolting, and this actually occurs⁸. Unfortunately, this advantage of late planting is more than offset by the great reduction in yield⁸, which is probably mainly due to the reduced leaf area caused by the cessation of leaf emergence with rapid bulbing. The small yields often given in warm seasons in Great Britain by 'early' strains of American origin, which are likely to have a low photoperiod for bulbing, may be similarly explained. Conversely, the large bulbs commonly produced by autumn sowing or spring sowing under glass may be attributed to the large leaf area produced before bulbing puts an end to the emergence of further leaves. The effects of day-length^{13,14} and temperature¹⁴ upon ripening intensify those upon bulbing onset.

Very high temperature ($21-27^{\circ}\text{C}$.) during the second season's growth not only prevents flowering by accelerating bulb development; it also exerts a direct effect even in the absence of bulbing (short days), suppressing both inflorescence initiation¹⁵ and the emergence of initials already present¹⁷. Such suppression without bulb development is unlikely to be of importance under field conditions in Great Britain, since high temperatures seldom occur except during the long days of summer.

Further Temperature Effects

Some further temperature effects may now be considered. Attempts to vernalize onion seed have so far given negative results, but the exposure of the seedlings to relatively high temperatures (mean about 21°C .) throughout the first season's growth results in sets which do not form inflorescence initials in the following spring¹⁷ and fail to flower when planted^{9,14}. In the data so far obtained this effect is, however, inseparable from a size effect, for owing to more rapid bulbing such sets are smaller than those produced at lower temperatures out of doors⁹.

The effects of high or low temperature during the whole or part of the storage period have proved somewhat complex. The effects upon flowering may be considered first. High temperature (30°C .) throughout the storage period (twenty-two weeks) not only inhibits inflorescence initiation during storage but also exerts a remarkable after-effect in preventing such initiation during the following season's growth¹⁷. Bolting may thus be almost completely controlled⁹. High temperature for the first eight weeks of the storage period also exerts an after-effect in delaying and greatly reducing inflorescence initiation and flowering; high temperature for the last eight weeks of storage, although it does delay initiation and flowering to some extent, is much less effective^{9,17}. It was deduced from indirect evidence¹⁴ that these effects of high temperature were not in the main brought about by the drying of the sets, and this has been confirmed by subsequent experimentation with controlled humidities. Cold storage (0°C .) for the first eight weeks exerts an after-effect in somewhat reducing inflorescence initiation and bolting; when given for the whole twenty-two weeks or the last eight weeks only, initiation is prevented

during treatment, but whereas in the former case subsequent initiation and flowering are reduced, in the latter they appear to be actually increased on return of the sets to normal temperatures^{9,17}. This last suggests that the onion plant is adapted to climatic conditions in which a cold spell in January–February is frequent. Greater survival in the field of sets from the late cold-storage treatment points in the same direction. The greater effectiveness of early high- or low-temperature treatment in preventing inflorescence initiation is of theoretical interest since such initiation does not begin before March.

The formation of new leaf initials during storage is also affected by the temperature, but these effects are mainly direct; the only after-effect found was a tendency for sets from treatments preventing initiation to produce initials more rapidly on return to normal temperatures¹⁷, thus resembling the effect of late cold storage on inflorescence initiation noted above.

High-temperature storage not only affects initiation of inflorescences and leaves, but also exerts remarkable after-effects in delaying bulbing and ripening^{9,14}. Such delay of bulbing allows of the emergence of more leaves¹⁴, the delay of ripening gives a longer growing season, and doubled or even quadrupled yields may result⁹. As in the case of flower initiation, the effects of early and late high-temperature storage (eight weeks) differ greatly, but here the difference is in the opposite sense: early heat treatment is almost without effect on bulbing and ripening, but the effect of late heat treatment is considerable; heat treatment throughout the whole twenty-two weeks period has a still greater effect. Recent experiments have shown that the increase in yield due to delay of bulbing and ripening is greater when drying of the sets in store is prevented by combining high humidity with the high temperature. The earlier deduction¹⁴ that these effects of heat-treatment were not due to drying is thus confirmed. The disadvantage of high-temperature storage that it causes shrivelling may apparently be overcome by the use of high humidities, but the delay of ripening which causes the increased yield may itself be a disadvantage in some seasons, especially in Scotland and northern England.

The effects of the environmental factors on flowering may be summarized as follows:

First, a direct effect of high temperature on flowering may be distinguished. Inflorescence initiation and emergence are inhibited, partially or completely, by exposure of the plants to temperatures above about 21° C., either during the whole period of growth from seed to set, during the whole storage period (October–March) or the earlier part, or throughout the second season of growth from replanted set to mature onion. The effect from seed to set may be solely due to the reduction of set size consequent on earlier bulb development; the effect in the second season is independent of day-length and hence of bulbing. When high temperature is applied during the last part of the storage period, it delays but may not ultimately reduce flowering. The effects of high storage temperature are not in the main due to drying of the sets.

Very low temperature (0° C.) throughout the storage period, or for the first part only, reduces flowering; but low temperature for the last part only results in a sudden flush of inflorescence initiation on return to normal temperature and appears actually to increase flowering. Medium temperatures

(10–15° C.) at any time during the life-history are apparently the most favourable to flowering, except for the accelerating effect of late cold storage.

On flowering, length of day has an indirect effect associated with bulbing as well as a direct effect. A temperatures high enough to encourage rapid bulbing in plants grown from sets, long days suppress inflorescence emergence; at temperatures low enough to prevent or delay bulb formation, long days accelerate the emergence of inflorescences by increasing the rate of scape elongation. The former effect of long days may thus be considered as indirect and due to the promotion of bulb development. Day-length is apparently without effect on flower initiation, and affects only the further development and emergence of the initials.

The more important effects on bulbing and ripening are these: The onset of bulbing is a response to the stimulus of long days and there is an interaction with temperature such that at lower temperature longer days are needed. Seedlings apparently need a longer photoperiod for bulbing than do plants grown from sets. At high temperatures bulb development is rapid and the emergence of new leaves ceases abruptly with its onset; at lower temperatures or on occasionally several more leaves may emerge. With a return to short days and (or) low temperature bulbing may be arrested and leaf emergence recommence without the usual dormant period. Long days and high growth temperatures not only stimulate rapid bulbing onset and development but also expedite ripening. Bulbing onset and ripening are delayed in plants grown from sets stored at high temperature, either throughout the winter (October–March) or for the last part only; heat treatment for the first part only of the storage period has little or no such effect. Such delay is increased if drying of the sets in store is prevented by high humidity.

It will be seen that a fairly comprehensive picture has been obtained of the control of development in the onion plant by the external factors of day-length and temperature. Further work is now being directed towards a more rigorous analysis of the internal rather than the external factors involved in bulb development and inflorescence initiation. The importance of such factors is indicated by the striking effect of size of set; large size is the outstanding characteristic leading to bolting, and the experimental fact that artificial reduction in size by the removal of swollen leaf bases prevents or delays bolting points the way to further progress in this analysis.

OBITUARIES

Prof Samuel J Record

THE death on February 3 of Samuel Record at the age of sixty-three will be keenly felt by people all over the world who are interested in wood, for, the name of any one individual deserves to be especially associated with the great revival of interest in wood anatomy during the past quarter of a century, and his. He very early realized the possibilities of the then unknown woody species of the tropics and the fundamental importance of the wood sample backed by adequate herbarium material. When, therefore, he was appointed professor of forest products at Yale in 1917, he set out to build up a collection of timbers that was to become by far the most important collection in the world. What was perhaps equally important was that he deliberately aimed at making a collection available to any genuine researcher in any part of the world. A deep and sincere desire to further the general cause of wood anatomy in any way that he could was characteristic of him and partly explains his world-wide popularity. Much as he did to this end by means of encouragement and advice must disappear with him, but he leaves more permanent memorials at least two of the instruments he used for carrying out this policy, the journal *Tropical Woods*, which he founded in 1925 and edited until he died, and the International Association of Wood Anatomists, for the creation of which he was very largely responsible and of which he was the first secretary-treasurer.

Record was an indefatigable worker, with a flair for seeing what most needed doing and an exceptional capacity for getting it done, either by his own labours or by interesting others. As examples of these talents we may cite first his books on the timbers of tropical America, the first of which, written with C D Merrill and published in 1924, marked a tremendous stride forward in knowledge of the trees and the timbers of this vast area, and secondly the standardization of the terms used in wood anatomy, for which he was largely responsible as chairman of the committee of the International Association of Wood Anatomists that ultimately achieved this end. He was always specially interested in the taxonomic aspects of wood anatomy, and his exceptionally wide knowledge of woods enabled him from time to time to make striking suggestions, particularly with regard to the position and affinities of individual genera or the botanical identity of timbers previously known only by their vulgar names, such as the tulipwood of Brazil. Record was educated at Wabash College, where he gained the M.A. degree and where he was later, in 1930, given an honorary doctorate in science. In 1915 he took the degree of master of forestry at Yale University and entered the U.S. Forest Service. In 1910 he went back to Yale and joined the forestry faculty. In 1917 he became professor of forest products and in 1939 Pinchot professor of forestry and dean of the School of Forestry. L CHALK

It is now nearly twenty-five years since I started the most interesting correspondence with Samuel J Record. The correspondence continued without interruption until the end of January this year, when I received his last letter. He had mentioned his plans for his retirement from the University, which he would be in June—how he was anticipating hav-

ing time for further research and the writing of a new book, and both he and I were looking forward to his expected visit to London, when we could again discuss matters relating to forestry, nomenclature, identification of timbers, and other subjects of mutual interest. We had much friendly controversy on these subjects, but generally our conclusions coincided. His energy and great knowledge, and the fact that he had at hand the very exhaustive collection of specimens of wood (more than thirty thousand) at Yale University, the accumulation of which was largely due to his personal efforts, was a great advantage, and from him I gained much useful information.

It was not only in his professional capacity that he excelled: he had wide interests, an active and tireless brain, a keen and subtle sense of humour, and I shall always remember with pleasure the long personal talks which cemented our friendship on the two occasions when he visited Britain.

His work "*Timbers of Tropical America*", the quarterly journal *Tropical Woods* of which he was editor, and many others were invaluable, but his outstanding work, "*Timbers of the New World*", provides much needed authoritative information about the woods and forests of Brazil and southern America, and is of surpassing value to the student of forestry and botany.

His sudden death at such a comparatively early age is a great loss, not only to his friends, but also to the world in general. ALEXANDER L HOWARD

Colonel M. J Godfery

WE regret to record the death at Torquay on April 9 of Colonel Masters John Godfery.

Colonel Godfery was a leading authority on European and especially British orchids. He carried out much research work in some of the more critical genera, including *Epipactis* and *Ophrys*. He contributed many papers to botanical journals, and in 1933 published his sumptuous "*Monograph of Native British Orchidaceae*", illustrated in colour by his wife. It will long remain the standard work on the group in Great Britain.

Colonel Godfery's most striking research related to the pollination of species of the genus *Ophrys*, much of which was carried out by watching cut flowers in vases on hotel verandahs in the Mediterranean region. He was able to confirm the observation, first made by M Pouyanne of Algiers, that certain species are pollinated by the males of insects which mistake the lip of the orchid for the female and, in performing the motions of fertilization on the lip, effect the pollination of the orchid. The male insects pay attention to the orchid lips only during a short period before the females emerge from their pupae, thereafter the orchid lips are left alone. This astonishing relationship between insect and flower has since been discovered also in an unrelated Australian orchid.

WE regret to announce the following deaths:

Dr Stanley Wells Kemp, F.R.S., secretary of the Marine Biological Association of the United Kingdom and director of its Plymouth Laboratory, on May 16, aged sixty-two.

Prof P Pelseneer honorary permanent secretary of the Royal Academy of Sciences of Belgium.

NEWS and VIEWS

Hydrographer of the Navy Retirement of Vice-Admiral Sir John Edgell, K.B.E., C.B., F.R.S.

ON April 30, Vice-Admiral Sir John Edgell retired from the post of Hydrographer of the Navy which he had held since 1932. Sir John has seen fifty-one years of service in the Navy, and had been in the Surveying Service for forty-three years. He held the post of hydrographer for longer than any other officer since Admiral Wharton (1884-1904) and had in fact done so for more than twice as long as any of his predecessors in the post save one. The work of the Surveying Service under Sir John in the major operations has been commented on again and again during the War, most notably perhaps by the late Admiral Ramsay in a report on the invaluable help given in the preparation for and the consummation of *D* day. But here it is more appropriate to refer to his interests in marine science generally. Sir John was elected F.R.S. in 1943, and was the first Hydrographer of the Navy to receive that high distinction since Sir Mostyn Field (1904-9). He has served as a member of the Port of London Authority since July 1941, and has now (it is understood) become acting conservator of the River Mersey. Shortly after he was appointed Hydrographer of the Navy, he became chairman of the Sub-Committee for Physical Oceanography of the National Committee for Geodesy and Geophysics, a position he still holds. It is well known that the "Discovery" Committee has, since its early days, had exceptionally valuable assistance from the Hydrographer of the Navy in the planning and running of its fine expeditions to high southern latitudes, and since Sir John succeeded Admiral Douglas on the Committee, his help has been very greatly valued.

Sir John Edgell also takes part in the Development Commission's work on fisheries research, and, by participation in the conferences of the International Council for the Exploration of the Sea, has become closely acquainted with foreign oceanographers. What has so far been said touches the past and the present, but it may easily be appreciated what great hopes British oceanographers have for the future, knowing that Sir John is applying his very best efforts to the end that Britain shall become possessed of a national institution of oceanography. He has already presided over meetings of scientific men working towards that goal, and prospects seem promising, largely thanks to his energetic interest, if Britain should once again take up a foremost position in the study of the sea, it will be greatly due to Sir John.

Rear-Admiral A. G. N. Wyatt

REAR-ADMIRAL A. G. N. WYATT, who succeeds Sir John Edgell, was born in 1893, being twelve years younger than his immediate predecessor. It is interesting to note that he is the first Hydrographer to enter the Navy after the withdrawal of *H.M.S. Britannia*, and, consequently, through the Royal Naval Colleges at Osborne and Dartmouth. He had the distinction of being selected as a chief cadet captain of his term, evidence that at an early age he displayed those qualities of leadership and character so noticeable in later life, and the award of the Royal Humane Society's medal for life-saving in a yachting disaster, when only in his early teens, was

indicative of his courage and powers of endurance. He went to sea as a midshipman in 1910. During the War of 1914-18, he served in destroyers and the battleship *Prince of Wales* as a watch-keeper, and, during the last year of the War, in command of a destroyer. As a young lieutenant, he was an expert boat-sailer, at which he excelled, even in a profession where a high standard of proficiency in that art was anticipated. It was not until 1918 that he decided on joining *H.M.S. Melisande* as a fourth class assistant surveyor, to devote his life to that service of which he was destined, twenty-seven years later, to become the head.

A distinctive feature in the new Hydrographer's career is his long period of service in charge of surveys at sea. He has commanded six of *H.M.S.* surveying ships, extending over a period of fifteen years, in fact, except for a spell of eighteen months as superintendent of charts at the Admiralty early in the present War, an appointment for a similar term as assistant hydrographer, he has been in charge afloat since 1926, when he joined his first surveying command, *H.M.S. Ormonde*. His hydrographic services have taken him to such varied parts of the world as Labrador, the Persian Gulf, Australia and New Zealand. During the greater part of the War, Admiral Wyatt was in command of *H.M.S. Challenger* in eastern waters. On relinquishing the command to take over his new duties, he received a letter of appreciation from the Lords Commissioners of the Admiralty for his services "in the valuable work of surveys completed under your direction since your arrival in the eastern theatre of war".

Educational Plans and Purposes

IN accordance with the general view that the study of education is a branch of sociology, *Nature* has distributed to its readers the discussions that led to the Education Act of 1944, and those that have so far resulted from that event. A new step has now been taken. The Ministry is to publish a series of pamphlets the first of which, bearing the title "The National Schools: their Plan and Purpose", has just appeared (London: H.M. Stationery Office, 1945. Pp. 6d net). Here the Ministry comes to close grips with the facts, the object of the pamphlet being "to set out some reflections relating planning to purposes in terms, not of the legal 'child', but of living children. Each kind of school is tersely dealt with, beginning with nursery and infant schools. Here, by the way, a curious *lapsus calami* attributes to Margaret Macmillan the great saying, "Educate every child as if he were your own". It was Rachel's saying, reverently quoted by her sister Margaret. The section on junior schools touches a sore spot when it remarks that far "the juniors have too often had to make do with the accommodation available after the seniors have been dealt with".

It is, however, when the pamphlet leaves the subject of primary and enters upon that of secondary education that the difficulties begin. The old identification of secondary and grammar-school education is traced to its historical causes, and blamed for unfortunate consequences. The promising junior technical schools, now in wholly insufficient supply, are explained, their vitality and successful development being attributed in part to "their freedom from the ties of any external examination". In the section on modern schools we read again that "free from the pressures of any external examination, the schools can work out the best and liveliest form

secondary education suited to their pupils" In fact, the Ministry seems to entertain definite views as to external examinations Cautious commendation is given to 'multi-lateral' experiments in organization We note, however, that in the reconstruction plans of certain counties, the letters 'G T M' frequently indicate that grammar, technical and modern education will be combined in one institution which will not be too large

Survey of Technical Education, 1944-45

IN his presidential address before the annual Whitsuntide conference of the Association of Teachers in Technical Institutions held in London, Mr C J Tirrell referred to some of the major problems now emerging from attempts to implement the 1944 Education Act in the technical field At the level of secondary education, past successful experience with junior technical schools will be of great value in the establishment of practical and realistic curricula, while the extension of the school-life under the Act to at least five years opens up a wide field of educational experiment in the technical secondary school, without prejudging the issue as to the extent to which the 'multi-lateral' idea may be applied An extension of the system of part-time day release is essential if practical experience and theoretical study are to be properly correlated, and there is an obvious need for a central council to bring together the universities, technical colleges and industry, if higher technological education is to maintain contact with industrial practice in all its stages of development Moreover, the great importance of craftsmanship to the many small industrial firms (some 100,000) seems to demand the establishment of new national certificates in craftsmanship which would ensure due attention being paid to the necessary technical background underlying all aspects of vocational training

Vocational Guidance

THE City of Birmingham Education Committee has issued a report of a research on "Scientific Vocational Guidance and its value to the choice of employment work of a Local Education Authority" The whole research, carefully and competently carried out, has extended over a period of no less than eighteen years, its general object being to ascertain what value there is in using psychological methods in aiding young entrants into industry, commerce and the professions, by showing clearly at the outset the likelihood of success or failure in certain branches of employment The report suggests that on the staff of a secondary school there should be at least one teacher competent to apply psychological tests, and that he or she should work in close co-operation with a specially qualified officer The resulting records could be used from time to time to enable decisions to be reached as to the course of a child's instruction, and towards the end of the child's school life to enable the juvenile employment officer, co-operating with the head and with the trained teacher, to give reliable vocational guidance The report, which includes the most elaborate details, may be obtained from the City of Birmingham Education Committee for 2s 6d.

British Council

Formation of Agricultural Department

AN Agricultural Department, which will be advised by a panel presided over by Prof J A. Scott Watson,

chief education and advisory officer of the Ministry of Agriculture, has been set up within the Science Department of the British Council, and Dr W T H. Williamson has been appointed director of the new Department Since the formation of the Science Department of the British Council in 1941, it has been found that many of the inquiries from abroad relate to agriculture In consequence, the Department of Agriculture has been created to control, co-ordinate and extend the work already begun in this direction Prominent agricultural scientific workers have made visits abroad under the auspices of the British Council and provided reports on the agriculture of some foreign countries It will be one of the functions of the new Department to follow up these reports and to provide expert information on how far the agricultural needs of the countries concerned can be provided for by the nations of the British Commonwealth It will present the achievements of British agriculture to other countries and keep them supplied with up-to-date information on all advances in practice and science Experiments have already been made in the distribution of original articles for reproduction in the technical press overseas

Dr Williamson has been adviser in agricultural chemistry to the University College of South Wales and Monmouthshire This post was a war-time creation, but he has built up a department which is now rendering valuable service to the farming community in South Wales and Monmouthshire Before the War he was, for eleven years, chief chemist to the Egyptian Ministry of Agriculture He was entrusted with the reorganization of the department and expanded it to more than three times the size of the original, housed in laboratories designed by himself and with greatly extended activities in the way of research, advisory work and routine analysis In 1937, in recognition of his services, he was created a commander of the Order of the Nile by the King of Egypt Dr Williamson has also served on the staff of the Edinburgh and East of Scotland College of Agriculture and the University of Aberdeen

Proposed North Polar Flights

SEVERAL flights over the north geographical pole have been made since Rear-Admiral R E Byrd, U.S.N., made the flight in 1926 using Spitsbergen as a base Most important was the Soviet expedition of 1937-38, but more flights are required, not probably for geographical discovery but for magnetic and meteorological research Flights over Arctic Canada have been made on several occasions It is now announced that a series of flights over both the geographical and magnetic poles are being made by an expedition from the Empire Air Navigation School of R A F Flying Training Command The aircraft used is the Lancaster *Aries* which was flown round the world last autumn by Wing-Commander D C McKinley Four new Rolls-Royce Merlin XXIV engines have been installed The base of the expedition is in Iceland, at least for the flights over the geographical pole A Canadian base will later be used for flights over the north magnetic pole in Boothia Peninsula The objects of the flights are stated to be: to examine the behaviour of compasses and automatic dead-reckoning gear, and to collect data on engine handling as well as magnetism and meteorology The plane carries food for four weeks, sledging gear and arctic kit The crew, all told,

numbers eight and includes a medical officer, Wing-Commander R. H. Winfield.

Future of Base Metals

LIEUT. COLONEL EDGAR PAM, president of the Institution of Mining and Metallurgy, delivered his presidential address at the annual general meeting of the Institution held on May 17. He pointed out that a not inconsiderable part of mankind as a whole depend for their living, or for their comfort and convenience, on base metals such as copper, zinc, lead and nickel, any important trend affecting their availability is therefore of great general interest. One effect of the War has been the concentration of a limited labour force on production at the expense of development work, the ore reserve of most important mines has been seriously depleted and, in spite of efforts intensified during the War, no ore bodies of real importance have been discovered for many years. Progress has been made in mining and metallurgical methods, but no epoch-making improvement stands to our credit since the development of flotation. With the relaxation of the demand for war uses, the supply in the near future should be ample, but within a few years a shortage seems indicated.

In order to help in the Colonies and even perhaps in Great Britain the opening up of new mines and industries, the Government should intensify activity along the following lines: (1) extend geological surveys, including the boring of promising regions; (2) support universities and technical schools by the equipment of laboratories, the provision of scholarships and, above all, by the assurance of such conditions of employment for staffs that the very highest grade engineers will be attracted to the posts; (3) improve transport facilities and help in building central power stations in selected areas; (4) improve the general education of the population, especially in the Colonies, with particular emphasis on health, safety and the dignity of labour; (5) give assistance in the development of promising new plant or processes which require finance beyond the power of industry to supply. The Institution has also a part to play. In the absence of a Chamber of Mines in London, it might consider setting up and fostering a permanent committee always available to help the Government or any other body at short notice by studying and reporting on technical, educational, health or welfare matters. Such a committee would also watch legislation and in some cases initiate discussion with the authorities in England or the Colonies.

Preventive Medicine in Mexico

DR. ANGEL DE LA GARZA BRITO, director of the Mexico School of Hygiene (*Bol. de la Oficina Sanitaria Panamericana*, 23, 607, 1944), maintains that medical education in Mexico, while good on the whole, has failed to keep up with the rapid progress in medicine and especially its social aspects. He declares that medicine is tending to become a business rather than a profession. The only guide for the average student is the material success of men in certain fields. Public health is a neglected branch, and the time devoted to it in medical schools ranges from 43 to 100 hours, which is decidedly insufficient. An attempt should be made to correlate the clinical, medical and surgical aspects of disease with the preventive social aspect. The students, for example, should visit the homes of

certain patients in company with a social worker to gain an insight into the influence of background upon disease.

Conference on Microfilm and other Documentary Reproduction

A CONFERENCE on microfilm and other means of documentary reproduction, organized by the Association of Special Libraries and Information Bureau (ASLIB Microfilm Service, Victoria and Albert Museum, London, S.W. 7), will be held at the Royal Society's Rooms, Burlington House, London, W. 1, on June 1 at 10.30 a.m. and 2 p.m., and June 2 at 10.30 a.m. On June 1 there will be papers and discussions on methods of documentary reproduction and its scope and use, and on apparatus and its use in library services and training. On June 2, a 'brain-trust' meeting will be held at which a scientific man, a humanist and a librarian will discuss with representatives of the legal profession, authors and publishers the existing copyright legislation in connexion with documentary reproduction. Tickets of admission can be obtained from the ASLIB Microfilm Service: single session, 7s 6d, whole conference, 15s for members, 11s and £1 for non-members.

The Night Sky in June

New moon occurs on June 10d 04h 26m UT and full moon on June 25d 15h 08m. The following conjunctions with the moon take place: June 6d 12h, Mars 4° N, June 6d 21h, Venus 3° N, June 11d 15h, Saturn 0° 6' S, June 16d 21h, Jupiter 4° S. In addition to these conjunctions with the moon, Mercury is in conjunction with Saturn on June 24d 11h, Mercury being 2° 2' N. On June 11d 18h 38m, Saturn is occulted by the moon, reappearance taking place at 19h 29 8m. No occultations of stars take place during the month. Mercury rises about 20 minutes before sunrise on June 1 and sets about an hour after sunset on June 30. The planet is in superior conjunction on June 16. Venus is a conspicuous object in the eastern sky in the morning hours, rising at 2h 22m on June 1 and 1h 30m on June 30. It attains its greatest western elongation on June 24. Jupiter sets about 1h at the beginning of the month and at 23h on June 30. Saturn is becoming difficult to observe and sets about an hour after the sun in the middle of June. There will be a partial eclipse of the moon on June 2, invisible at Greenwich, but visible in the antarctic regions, Australia and eastern Asia. Summer solstice is on June 21d 19h.

Announcements

PROF. W. J. HAMILTON, professor of anatomy at St. Bartholomew's Hospital Medical School, has been appointed regius professor of anatomy in the University of Glasgow.

PROF. C. H. LANDER, professor of mechanical engineering at the Imperial College of Science and Technology, London, and formerly director of fuel research, Department of Scientific and Industrial Research, has been awarded the Melchett Medal for 1945 of the Institute of Fuel in recognition of his work on fuel during the past thirty years.

ERRATUM.—The new head of the Science Department at the South-East Essex Technical College, Dagenham, is Dr. J. F. J. Dippy, not Dr. Dippy as printed in *Nature* of May 12, p. 571.

Inheritance of Morphological Characters in the Sperms of Cattle

THE purpose of the present note is to record two findings which suggest the inheritance of certain morphological characters in bovine sperms as met in New Zealand

(1) There is a fairly constant difference in the shape of the Friesian or Shorthorn sperm-head when compared with the Jersey. After a lengthy experience, I am able to distinguish between the two kinds of sperm-smears with a large measure of accuracy. In a recent test, sixteen samples were submitted by a supervising meat inspector, who stated that the samples were "Friesian and Jersey". Differentiation was correct in each of the sixteen smears. Friesian and Shorthorn sperms usually have wider heads than Jersey sperms. Recognition of differences in other breeds, such as Ayrshires, Herefords and Polled Angus, has not been sufficiently constant, so far, to warrant the statement that these breeds may be picked from Jerseys to any significant degree, although Herefords and Ayrshires have been separated from Jerseys occasionally. It is thought that Herefords might usually be thus differentiated from Jerseys by the slightly wider sperm-head.

(2) The possible inheritance of other morphological characters within the Jersey breed may also justifiably be reported because of their importance from association with poor fertility. I am convinced that the presence and abundance of sperms with the abnormal character of re-turned tails and of sperms with narrow heads are largely determined by heredity, the two types of abnormalities being inherited separately. I am especially impressed by the fact that bulls, the ancestry of which led me to expect a certain sperm-picture, have shown the anticipated abnormality to a marked degree on examination. More particularly has this been the case in bulls which belong to the family known as the *Z* family and in the pedigrees of which bull *Z* figures on their sire's and dam's sides.

On occasion the sperm-picture has been foretold when the pedigree of a bull has been known, but the analysis of pedigrees so far performed does not entirely convince critical friends working in live-stock genetics. Many bulls prominent in pedigrees have long been dead and were never within range, and they stand far back in most pedigrees, though such bulls may appear several times in the same pedigree. These foundation bulls have many descendants, therefore any bull has a good chance of tracing back to one of these foundation sires and I hear more readily of bulls of poor fertility than of good ones. Caution must therefore be exercised in claiming inheritance, but further investigation is now my main concern.

To show the origin of the suggestion of inheritance of certain types of sperms, the three pedigrees which pointed the clue are given below

It was noticed that the sperm-pictures of these three bulls were similar and, on inquiry being made, it was found that they were closely related, the bull *Z* being a paternal and maternal ancestor, in direct male line, of the sire and dam of all three bulls. Bulls 885 and 1334 are half-brothers through their dam *P*, while bull 1334 is also half-brother to No. 1559 through their common sire *S*. The type of sperm notable in semen from these three related bulls is similar to that shown by Williams in "The Diseases of the Genital Organs of Domestic Animals" (1939 edition, p. 376, Fig. 125), this sample was collected by me, and the bull was in the same *Z* family as the three whose pedigrees are shown above. This type of abnormality is known here as 're-turned tails' because the tails are turned back past the head, but it is not suggested that this is the best possible terminology. Another family, prone to narrow heads as the particular sperm-type, is well depicted in the same work by Williams (pp. 380 and 381, figs. 128 and 129), both samples were collected by me and belong to the *D* family, the particular sperm-type of which, fortunately known to have been that of the foundation bull, *D*, himself, is narrow heads. It may be mentioned that the samples of which Williams gives photographs were collected in 1930 and 1933. Fig. 125 indicates a bad bull, Figs. 128 and 129 indicate total sterility. On the data analysed, it appears that bulls which have bull *Z* as paternal and maternal ancestor are eight times as likely to have a sperm-picture somewhat similar to Fig. 125 by Williams as are bulls not connected with *Z* for several generations back. Similarly, bulls which have bull *D* as paternal and maternal ancestor have five chances to one of showing many narrow heads when compared with the above-mentioned lot known as 'other bulls'. In the matter of fertility, of all bulls whose pedigrees are known, the *Z* family shows 29 per cent sterile and the *D* family 18 per cent sterile, as against the 'other bulls' group which shows 13 per cent sterile.

Certain important factors in this work, namely, the ages of the bulls generally, the ages of the sterile bulls, the methods of assessing fertility and the reasons for examination, as well as details concerning other related groups, are to be discussed in a later paper. It is agreed by the critical friends mentioned above that the slowness of breeding work with large domestic animals and the value of the economic stakes make it desirable to inform fellow-workers of strong suspicions when much time may be necessary for substantiation. The facts that different breeds of bulls can be recognized by their particular sperm-morphology and that the sperm-morphology of certain individuals of different families or strains in one breed can be anticipated seem to point to inheritance of those special types. During the past fifteen years it has not been possible for me to point to any other cause, which would bear criticism, for the lack of fertility shown by so many young bulls. The present contribution is the more permissible because of the rise of artificial insemination. By that means defective fertility might be spread widely. It is hoped that other workers may be stimulated to pay attention to the hereditary basis of abnormal sperm morphology or of some character of semen which can be correlated with impaired fertility.

Calculation of the Results of Microbiological Assays

IN view of the increasing use of microbiological methods for the assay of vitamins, amino-acids, etc., I think it important to direct attention to the fact that the method at present employed of computing from the experimental data an estimate of the potency of the material assayed not only is theoretically unsound, but also may in practice give a result which is materially in error.

The procedure originally described by the pioneers in this field, and which has now become customary, is as follows. Tubes are put up containing several graduated doses of a dilution of the pure nutrient factor concerned (hereafter referred to as Stand Prep) and three or four different doses of the extract being assayed (Test Prep), besides the 'blank', in which no addition to the basal medium is made. After the usual incubation, and estimation of the growth in all tubes in terms of a titration, turbidimetric reading, or other measurement—for the sake of generality this will be referred to as the 'response'—a curve is plotted relating the dose D of Stand Prep to the response Y . From this curve the amount of the nutrient factor corresponding to the response y obtained from each dose d of Test Prep is read off. Three or four estimates of the potency of the Test Prep are thus obtained, and provided these do not differ among themselves by more than a certain amount (± 10 per cent is usually regarded as reasonable agreement) their average is taken as the final result.

It will be noted that the curve relating dosage of Test Prep to response is not plotted—or if it is, it does not affect the final calculation. I therefore refer to this as the 'single-curve' method of calculation.

The relation between D and Y is, over a certain range of dosage-levels, very closely linear in many microbiological assays, so that this equation is true

$$Y = A + BD \quad (1)$$

B is the 'slope' of the line and A is the value of Y when $D = 0$, that is, the intercept on the Y axis made by the line when produced backwards. In some cases A practically coincides with the 'blank', which is then a point on the Stand line, but in other assays the 'blank' is off the line.

Now if the response to the Test Prep is due to its content of the pure nutrient factor provided by the Stand. Prep., without augmentation, diminution or modification by anything else—and this hypothesis lies at the root of all assays—the curve relating dosage d to response y must be identical with the Stand

curve except that the scale is different, and the ratio of the scales is the only sound measure of the relative potencies of the two preparations. Thus if (1) is true of the Stand Prep, then the following form of equation must hold for the Test Prep

$$y = a + bd \quad (2)$$

and four important conclusions may be drawn.

(1) If the Stand points lie close to a line, so should the Test points also. Marked lack of linearity would render the assay suspect.

(2) The ratio of the potencies of the two preparations is given by b/B , the 'slope-ratio' of the two lines, and the potency of the Test Prep calculated from the slope-ratio will be a valid statement of the mean potency, over the range of linearity of the Stand Prep, irrespective of the shape of the curve outside these limits, provided that the hypothesis above referred to is true.

(3) Since the constants a , A , are independent of the kind or size of dosage given, they must in theory be equal. This means that if the Test and Stand lines are plotted on one graph—the scales chosen for each being immaterial, so long as they have the same origin—they should intersect on the axis of response, and any difference between them, if greater than is to be expected from the chance operation of experimental error, casts doubt on the validity of the assay; that is, it suggests that the basic hypothesis is not true. Whether the difference ($A - a$) found in any given assay is, or is not, big enough to cause suspicion can, and should, be tested statistically, but there is no space to go into this now.

(4) Mathematical investigation shows that unless ($A - a$) is approximately zero, so that the two lines intersect on, or very close to, the axis of response the 'single-curve' method of calculation may give results which, although they may agree with each other within 10 per cent, nevertheless differ from the 'slope-ratio' result by much more than this percentage. It is true that in such a case the whole assay is suspect and neither method may give a true result, but it is very likely (see below) that the 'slope-ratio' result is much nearer the truth than any other.

The following numerical example from one of several assays, the protocols of which were recently shown me, demonstrates that the matter is not merely of academic interest.

Dose	Riboflavin (μgm)					Test prep (mgm)		
	Blank	0.05	0.10	0.15	0.20	3	4½	6
Mean response (ml)	1.06	2.50	3.80	5.12	6.59	4.02	4.95	6.11

The Stand points will be found to lie very close to a line which includes the 'blank'. The three Test responses, read off from the line, lead to riboflavin contents of 35.7, 31.6 and 30.7 μgm per gm respectively—mean 32.7 μgm per gm. The three results are all well within 10 per cent of the mean.

The 'slope-ratio' method involves the plotting of the Test points as well. They also lie close to a line but—unlike the Stand line—it does not pass through the 'blank', ($A - a$) is, in fact, approximately 0.85 ml. The slopes of the two lines should be taken from the graph, but the following approximate computation gives in the present case an almost exact result. The increase in response from 0 to 0.20 μgm of riboflavin is $6.59 - 1.06 = 5.53$ ml, which is at

the rate of 27.65 ml per μgm . The increase in response from 3 to 6 mgm of Test Prep is similarly $11 - 4.02 = 2.09$ ml, or 696.7 ml per gm. The riboflavin content of the Test Prep is given by the ratio of these two slopes, namely, $696.7/27.65$ or $2.52 \mu\text{gm}$ per gm. Thus the result obtained by the 'single-curve' method, $32.7 \mu\text{gm}$ per gm, is nearly 10 per cent too high.

The explanation of the discrepancy is shown by further analysis of the data. The first and second additions of $2 \mu\text{gm}$ of riboflavin produced increases in response of $3.80 - 1.06 = 2.74$ and $6.59 - 3.80 = 2.79$ ml, respectively, that is, nearly equal increments at the first and second additions of 3 mgm of Test Prep will be seen to have given incremental responses of 2.96 and 2.09 ml, which are much too unequal for the difference to be due merely to random errors. It may be that the first 3 mgm of Test Prep provided the bacteria not only with riboflavin, but also with some other factor they needed which was *partially* deficient in the basal medium, while the second 3 mgm provided riboflavin only, the deficiency in the other factor being now fully made up. This possibility is strengthened by the fact that the response to the second 3 mgm can be subdivided by using the response to a dose of $4\frac{1}{2}$ mgm, and the two $1\frac{1}{2}$ mgm increments are then seen to have produced increases in response of 0.93 and 1.16 ml, respectively—that is, the difference is now within the limits of experimental error, so that the disturbing influence, whatever it may be, ceases to have effect after the first 3 mgm of Test Prep have been added. Mathematically, the assay as a whole is suspect; if there is anything in this argument at all, the incremental responses to the second 3 mgm of Test Prep should be a fairly good measure of its riboflavin content, even when the incremental response to the first 3 mgm is not. This is the reason why I state above that even in a theoretically invalid assay, the 'slope-ratio' result may be reasonably accurate.

If other workers will go back through their records, plot their Test Prep lines on the same graph as their standard Prep lines, and recalculate their results by the 'slope-ratio' method, I believe they will find many cases where $(a - A)$ is suspiciously large, and am sure that in such assays the 'slope-ratio' calculation will lead to a result markedly different from the true one. In any event, the use of the 'single-curve' method should be abandoned, as having no advantages and being inherently unsound, and the standard Prep line should always be plotted, if only to give an 'eyesight' test of the validity of the assay.

Thiol - Vitamin K Mechanism in the Clotting of Fibrinogen

FROM an investigation into the chemical mechanisms involved in the conversion of fibrinogen into fibrin gel, it appears that the conversion occurs in at least two stages. The first stage is marked by the liberation of thiol groups in the fibrinogen molecule. The second stage is an oxidation of these thiol groups, which unite to form disulphide linkages with adjacent molecules. It has now been found possible to isolate three intermediate

products which react when thrombin clots fibrinogen. Thrombin can be divided into two active components which have separate and distinct functions. Neither component will convert, *per se*, fibrinogen into fibrin, but the mixture of the two will readily clot fibrinogen.

Thrombin component A reacts with fibrinogen liberating thiol groups to form an intermediate, fibrinogen B, between fibrinogen and fibrin. This intermediate is formed during normal clotting in approximately a tenth of the time required to form a fibrin gel. The intermediate, when isolated, can be clotted by thrombin component B, or can be immediately converted into a fibrin gel by minute amounts of 2-methyl-1 4-naphthoquinone in 50 per cent alcohol solution.

Examination of the gels thus produced by either thrombin or 2-methyl-1 4-naphthoquinone using dark-ground illumination and a magnification of 900 diameters showed finely fibrillary gels, and no differentiation could be made between the two.

Evidence suggests that vitamin K is either a prosthetic part of thrombin component B, or that it converts a protein fraction into an oxidation-reduction system with a potential in the vicinity of that of vitamin K. Sensitive colour reactions^{1,2} suggest that a quinone structure is present in the thrombin molecule. Both reagents give a slight reaction when applied to the ether extract of thrombin which has been digested by trypsin.

The reaction between thrombin and fibrinogen can be illustrated by the following scheme:

Evidence in support of this scheme is both polarographic and chemical. (1) Polarographic analysis shows a relatively large number of thiol groups in fibrinogen B. (2) Similar analysis shows relatively few in native fibrinogen. (3) The isolation of thrombin component A, which will convert native fibrinogen into fibrinogen B, but will not clot it. (4) The isolation of thrombin component B, which has no reaction upon native fibrinogen, but which will convert fibrinogen B into a fibrin gel. (5) Addition of small amounts of thrombin to native fibrinogen temporarily increases the concentration of thiol groups. (6) Fibrinogen B will gel immediately upon the addition of $1 \mu\text{gm}$ of 2-methyl-1 4-naphthoquinone in 50 per cent alcohol per ml of fibrinogen solution, but not upon the addition of alcohol alone. Native fibrinogen is unaffected by an excess of 2-methyl-1 4-naphthoquinone. (7) When thrombin and fibrinogen have been reacting for at least a tenth of the normal clotting time, clotting is immediate if an excess of 2-methyl-1 4-naphthoquinone is added. (8) It is essential that the naphthoquinone be added after the thrombin, since the alcohol in which the naphthoquinone is dissolved inhibits the formation of fibrinogen B. (9) Thrombin digested with trypsin gives a colour-reaction characteristic for naphthoquinone with 2 4-dinitrophenylhydrazine. (10) The clotting of fibrinogen by thrombin is greatly accelerated by peroxidase (which could re-oxidize the naphthol form of naphthoquinone resulting from the oxidation of thiol groups). (11) Fibrinogen in both forms catalyses the iodine-sodium azide reaction, a function of $=\text{S}$

and —SH linkages, but fibrin does not (—S—S— linkage does not) (12) Fibrin is readily soluble in sodium sulphide, which disrupts —S—S— linkages (13) Blood clotting can be inhibited by an excess of thiol compounds and by substances which react with thiol groups (a) mercury compounds, (b) arsenic compounds of the arsenoxide type, (c) cyanides (14) The immediate oxidation of thiol compounds by 2-methyl-1,4-naphthoquinone can be shown polarographically

It is not suggested that the conversion of fibrinogen to fibrin occurs when one molecule of fibrinogen is united to another by a single —S—S— linkage, but that the fibrinogen molecule contains many potential —SH groups, and that these unite in a definite pattern forming long chains and ultimately give rise to the typical fibrin gels

Details of the experiments which gave rise to these findings will be published elsewhere

Methionine and the Fatty Liver of Infant Pellagrins

On a previous occasion, we were able to demonstrate that the intensely fatty liver is an invariable concomitant of pellagra in infants. This fatty liver responds poorly to a balanced diet with, or without, supplements of vitamin concentrates, chiefly of the B₃ complex, it recovers slowly when treated with crude liver extract but is rapidly and completely healed by ventriculin^{1,2}.

In order to obtain further information concerning the nature of this fatty liver, we decided to test the effects of methionine under controlled conditions. The amount of methionine available to us was just sufficient for two cases. One child was three years of age and the other fifteen months. As a control, we used another fifteen months old pellagra. The three cases were selected, not only on the basis of the clinical criteria on admission, but also on the similarity of the liver lesion as determined microscopically.

The three cases were submitted to biopsy within an hour of admission to hospital, and when it was established that the fragment of liver was intensely fatty, with almost every cell containing a single, large globule of fat, such as is described previously in our category 1², or type 1, *b* variety³, treatment was then instituted. The cases were put on the same basal diet of mealie meal (maize) porridge and half-strength milk and, in two cases, methionine was added in amounts stated below. Biopsy of the liver was performed in all cases soon after admission, a day after the last dose of methionine or, in the case of the control, at the end of one week.

Case 1 was a three-year-old infant. A total of 8 gm of methionine was administered orally over four days. The treatment was stopped because the clinical condition deteriorated and the oedema became intensified. The liver, at this stage, was even worse than on admission to hospital. Treatment with a full diet and ventriculin resulted in the disappearance

of the oedema fluid within four days, and the liver fat became absorbed, but at a much slower rate than in cases not pre-treated with methionine.

Case 2 was aged 15 months. A total of 11 g of methionine was administered orally over seven days. The clinical condition did not improve and the oedema became intensified. Another biopsy of the liver was performed and the fat was almost abundant as at the outset of the treatment. At the end of the first week, when the administration of methionine was stopped, the ventriculin treatment was instituted. This child also recovered slowly.

Case 3 was the control and also 15 months old. On admission, the liver was indistinguishable histologically, from those of Cases 1 and 2. The baby received no treatment other than half-strength milk and mealie meal porridge. Although the clinical condition did not improve, the liver, at the end of one week, did show some deterioration. After treatment for one week with ventriculin, the child made a rapid but uneventful recovery.

In all cases the livers were examined by fluorescence microscopy. Typical vitamin A fluorescence was not observed in the Kupffer cells. However, many of the big droplets of fat showed a dull greenish white fluorescence. Popper and Chinn⁴ maintain from their experiments in rats, that vitamin A fluorescence disappears from the liver in cholesterol deficiency, but in human infants we have found that the fluorescence of the fat droplets in the liver remains, even after treatment with methionine, and the Kupffer cells remain free from vitamin A fluorescent material.

From this investigation we conclude (a) In conjunction with a high carbohydrate diet, methionine in the amounts used over a short period, does not remove the fat from the livers of human pellagrins in a manner comparable with that described by ventriculin. (b) Fluorescence of the fat droplets in the livers of infants does not imply that they will respond to methionine. (c) Methionine, under present conditions stated above, neither removes the oedema fluid nor does it lead to clinical improvement. (d) High carbohydrate diet in infants has not the lipotropic action in children which it has in many adult pellagrins⁵. (e) Either methionine, in the amounts used over 4–7 days, is incapable of acting as a lipotropic substance in infant pellagrins, or it requires some additional dietary substance to exert its lipotropic effect. Channon *et al*⁶ suggested from experiments in rats. (f) Ventriculin, in conjunction with a full diet, is still the best treatment for pellagra in infants. The limited amount of methionine available to us (20 g) prevented us from carrying out more exhaustive experiments.

We are indebted to Mr Brown, of Glaxo Laboratories, Johannesburg, for the methionine.

Concentration Regulation and Volume Control in *Lumbricus terrestris* L.

PREVIOUS work on these topics (Adolph and Adolph¹, Adolph², Maluf³, Wolf⁴, Maluf⁵, Wolf⁶) has assumed that the earthworm is a freshwater animal, and that volume changes are inversely proportional to changes in the concentration of the body fluids. Soil analyses (Russell⁷) show that the osmotic pressure of soil is higher than the above workers have assumed. Moreover, in the case of another annelid, *Nereis diversicolor*, Beadle⁸ has shown that the body volume can remain constant while the body fluid is diluted. Both assumptions may therefore prove unsound.

Earthworms were kept in filter paper moistened with saline solutions, and the concentration of the body fluid was determined. The body fluid used for each determination consisted of a mixture of the coelomic fluid and blood of four worms. This was analysed for chloride, and the conductivity of a warmed diluted sample was measured. Changes in weight were also followed, the worms being weighed in air after gentle rolling on filter paper. Equilibrium body fluid concentrations are given in the upper graph, and equilibrium changes in weight in the lower graph.

The upper graph shows that the animal possesses well-developed powers of concentration regulation, which are equally effective in media of widely different ionic compositions. It can maintain a hypertonic body fluid in 'dilute' media, and a hypotonic body

fluid in 'concentrated' media. Few animals so far investigated are able to maintain hypotonic body fluids, and in each case it has been supposed that they have evolved from fresh water (see Beadle⁹). It is possible to argue in a similar manner that *Lumbricus* has evolved from a freshwater to a semi-terrestrial habitat. The earthworm is certainly no longer a freshwater animal in so far as its osmotic relationships with the environment are concerned.

The lower graph shows that body weight (that is, body volume) depends on the nature and concentration of the medium. Comparison with the other graph shows that in many media, volumes and concentrations both increase. Volume control and concentration regulation are apparently not intimately correlated, at least under the present experimental conditions. Almost all the previous work is based upon an inverse relationship between concentrations and volumes, and therefore some revision of past conclusions may be necessary.

Pigmentation of Orthoptera

THE wings and skin of the green *Mantis religiosa* L. contain not a green but a yellow and a blue pigment. The yellow pigment is of a carotenoid character, soluble in alcohol, ether, chloroform, acetone, benzene, etc. It is insoluble in water. The parts treated with the ether leave their blue pigment in the water. This pigment is precipitated from the aqueous solution by ammonium sulphate to saturation. It is very probably a chromo-protein (*orthopteroerythrin*). It is immediately decomposed by a few drops of cold concentrated acetic acid.

The blue colouring matter (*orthopteroerythrin*) passes into chloroform, ethyl acetate or amyl alcohol. These solutions give the Gmelin reaction of biliary pigments (violet rings, then green) with strong nitric acid. The aqueous solutions show a strong biuret reaction.

The phytophagous Orthoptera, such as *Acrida tigris* L. and *Phaneroptera quadripunctata*, have the yellow and blue components, while in the hind wings of *Oedipoda caerulescens* and *Oed. schottii* there is only water-soluble pigment.

The green haemolymph also contains the blue and yellow components. A green drop, absorbed by filter paper, turns blue in an organic solvent. A blue drop is in turn dissolved in water.

The bright red hind wings of *Oedipoda miniata* Pall., as well as an orange-yellow carotenoid, contain also a red pigment soluble in water. It is probably a chromo-protein (*orthopteroerythrin*). It is decomposed by acetic acid, like the blue pigment. The red colouring matter (*orthopteroerythrin*) gives the Gmelin reaction, while the aqueous solution shows a strong biuret reaction.

Easy Demonstration of Nuclear Division in an Animal Cell

THE chance appearance of a perfectly stained nematode egg in a smear of intestinal Protozoa prepared by a student (Marjorie Ind) led to the making of preparations *ad hoc*. The details of nuclear division in these were clear, and as cytology is strange ground to me I consulted Dr. C. D. Darlington.

The worm first treated was *Nematospiroides dubius* Bay. (Strongyloidea), kindly identified by Dr. H. A. Baylis. It is a very common parasite of the upper part of the small intestine of the woodmouse, *Apodemus sylvaticus*, pink in colour, coiled into a characteristic tight spiral column, the female worm being about 10 mm. in length. The eggs segment to eight cells *in utero*. A mouse may yield more than a hundred worms, and in the colony in my garden all seem to be infected. They are caught by a box trap with oatmeal on the floor and a raisin on the trigger.

Owing to the large size of the eggs of the worm the treatment is rather slow. Put one to four female worms on a coverslip with just enough saline to hold them; cut across repeatedly with needles to release eggs and pieces of oviduct containing eggs and sperm; smear with a stroke of the needle; float film downwards on to freshly mixed alcoholic Bouin's fluid; reverse after a minute and fix for three hours. The smear is allowed thirty minutes at each alcohol change and staining is by Delafield's haematoxylin, port wine colour, overnight. Differentiate with 1 per cent acid alcohol for three hours; blue the film in slightly ammoniated alcohol of the same grade; clear with clove oil for thirty minutes and allow a few minutes in xylol before mounting.

The common strongyloid worm, *Oswaldocruzia* sp., of the frog intestine answers equally well, and no doubt many other small nematode worms will do so. This opens up a field of investigation, as Dr. Darlington says that, in spite of the classical example of *Ascaris*, very little is known about the chromosomes of nematodes. The clearest picture is given of meiosis in the maturing eggs, a series of several often lying in a piece of oviduct and showing successive steps. There are six bivalents all showing terminal chiasmata, and at late metaphase these appear like a circle of large diplococci which can be counted with the 1/6 objective (see photomicrograph). Mitosis also can be followed in the segmenting egg, but is less clear in detail than meiosis as the chromosomes appear

as a ring, or double ring, of minute granules on quite clear spindle. Chromosome behaviour is much the same in both the species of worms examined. Dr. Darlington considers that a study of meiosis will prove more important than the mitosis which does not show the features (that is, diminution) of the *Ascaris* type.

Methods of preparing smears for chromosomes are of course, well known, but the application to nematode worms appears to be new, or not generally known. It is for its possibilities for class work that this casual discovery makes its appeal to me. The zoologist need no longer go to plants for the demonstration of nuclear division. The worms from wild mice, voles, frogs or toads are available at any time of the year. No skilled dissection is required and the technique is simple. The student who has helped me with the preparations was successful in her first attempts with little conning. It is hoped that some worker who has access to living hookworms, *Ancylostoma* and *Necator*, will make tests with these and report on the results. The eggs are very similar to those of the worms here dealt with and should be even more readily manipulated.

Species of *Lucilia* Attacking Sheep in South Africa

Two species of *Lucilia* are stated to be associated in the sheep blowfly complex in South Africa. One of these, *Lucilia cuprina* Wied. is regarded as the main primary fly which produces strike in living sheep. *L. sericata* Mg., on the other hand, is not considered as important in this respect, although known to be the chief cause of strikes in Europe.

The systematic separation of the two species rests mainly upon a difference in the colour of the femur of the fore-leg in the adult fly. In *L. cuprina* this is bright green; in *L. sericata* it is black. In *L. cuprina* the abdomen is green with a bronze sheen; in typical *L. sericata* fly it is a distinct blue-green.

In any batch of field material containing both species, there is nearly always a gradation in the colour of both femur and abdomen so that, with certain individuals, a correct classification is difficult. The colour of a fly can also vary with the composition of the larval food supply. In addition, colour is often misleading, and in some cases is largely dependent upon the opinion of the observer. It is therefore not a scientific criterion.

The two species of flies are biologically identical. Both are attracted to, and breed upon, carrion, and both occur in wounds on the living sheep. Moreover, they interbreed readily in captivity and there is little doubt that they also do so in Nature.

In breeding experiments carried out at this Laboratory, crosses were made in both directions which gave rise to fertile progeny. In the F_1 generation, the green femur of *L. cuprina* and the blue-green abdomen of *L. sericata* proved to be dominant, all the progeny having these two characters. In the F_2 generation segregation occurred, giving individuals of three types, namely, (a) with green femur and bronze green abdomen (typical *L. cuprina*); (b) with green femur and blue-green abdomen (hybrids); (c) with black femur and blue-green abdomen (typical *L. sericata*).

In a typical batch of F_2 progeny from such

MATURING EGGS OF *Nematospiroides dubius* (NEMATODA) SHOWING THE NUCLEUS IN MEIOSIS: POLAR AND SIDE VIEWS. $\times 500$. PHOTO. BY J. MANBY.

cross we obtained 57 individuals of (a), 201 individuals of (b), and 62 individuals of (c). This gives an approximate ratio of 1:4:1. This ratio was reasonably constant with all batches examined. Colour, therefore, behaves as a Mendelian character with tetraploid characteristics.

In practice, this result means that colour cannot be used legitimately as a means of separating the two species and, if this is the only character available, they should be looked upon as, at the most, two forms of the same species.

Field material always contains individuals which conform in appearance to the hybrids of the F_2 generation mentioned above. Thus, if all flies exhibiting a green femur are to be put down as *L. cuprina*, we are including under this form a proportion of the population which, strictly speaking, cannot be singled out as either *L. cuprina* or *L. sericata* but which is, in reality, the hybrid form. Because of this, it is more than probable that records dealing with *L. cuprina* bred from living sheep include these hybrids. This would explain the very high proportion of *L. cuprina* said to occur on sheep as contrasted with the low numbers of *L. sericata*. In reality, it is more likely that the typical forms occur in approximately equal numbers.

If this is accepted, the conclusion that *L. cuprina* is the main primary fly is incorrect. Although Australian workers regard the crossing of the species in the field as an unlikely contingency, they advance no convincing reason for this opinion. As the hybrid form appears in field collections, we are more justified in concluding that it does take place on an appreciable scale.

Origin of a Toxicity to Mycorrhiza in Wareham Heath Soil

CONSIDERABLE interest has been aroused by the researches of Rayner¹ and Neilson Jones² on a growth failure of conifers at Wareham Heath, Dorset. These workers have demonstrated that this growth failure is associated with the development, in the soil, of a definite toxicity to the mycorrhizal fungi normally associated with these trees, and have presented convincing evidence that the toxicity is of biological origin. Neilson Jones has suggested that it may be due to production of hydrogen sulphide by aerobic sulphate-reducing bacteria. We have now been able to show that the toxicity may be due, at least in part, to the production of fungistatic organic substances by certain *Penicillium* spp. characteristic of the Wareham soil microflora.

Our observations on the mould flora of a sample of Wareham soil, as determined by plating on Jensen's agar, confirm those of Neilson Jones, such organisms as *Mucor* spp., *Trichoderma viride*, *Penicillium chrysogenum* and *Fusarium* spp. abundant in meadow or arable soils, are virtually absent. The mould flora is almost restricted to certain *Penicillium* spp., the most abundant of these being several strains of *P. janczewskii* Zai, a number of slightly differing isolates which are tentatively attributed to *P. janseni* Zai and a number of strains distinct from *P. janczewskii* Zai but clearly falling into the group described by Thom as the *P. nigricans-janczewskii* series.

Cultures of these moulds have been grown on a range of liquid media and these have been periodically assayed for antibacterial activity by serial dilution tests with *Staphylococcus aureus* and *Salmonella typhi*, and for fungistatic activity by a spore germination test with the conidia of *Botrytis allii*. Using this technique, we have found that the isolates provisionally identified as *P. janseni*, after seven days incubation at 25° C on a Raulin-Thom medium, produce a culture filtrate which will inhibit germination of *B. allii* conidia at a dilution of 1 in 64, and growth of *Staphylococcus* or *Salmonella* at similar dilutions. The isolates referred to the *P. nigricans-janczewskii* series, on the same media and under similar conditions, will produce culture filtrates inhibiting germination of *B. allii* conidia at a dilution of 1 in 32, but requires higher concentrations to inhibit growth of *Staphylococcus* or *Salmonella*. We have not been able to demonstrate the production of inhibiting substances, under these conditions, by the *P. janczewskii* isolates, but we have found that on media containing organic nitrogen, culture filtrates are produced having a peculiar distorting effect on germ-tubes of *B. allii*, even at dilutions of 1 in 500.

The active antibiotic substance produced by our strains of *P. janseni* has been isolated by extraction of the culture filtrate with chloroform, evaporation to dryness at reduced pressure and crystallization from ethyl alcohol. The substance thus obtained crystallizes from ethyl alcohol in small colourless prisms which appear throughout the liquid in clusters resembling pairs of wings. It decomposes without melting at about 205° C, and the decomposition products melt at about 225° C. The analysis of this substance (Table 1) agrees with that of gliotoxin^{3,4,5}.

TABLE 1

%	I Found	II	Calc for C ₁₅ H ₁₁ N ₇ S ₂ O ₄
C	48.1	47.9	47.8
H	4.5	4.5	4.3
S	19.4	19.7	19.7
N	8.4	8.9	8.6

However, authentic gliotoxin produced by *Trichoderma viride*⁶ crystallizes in separate prisms from ethyl alcohol, while large rosettes of prisms are formed on the walls of the container. Although there is a considerable difference in the appearance of the two specimens, a comparison of their properties has shown the two to be identical. The specific rotations agree within the limits of experimental error. For a solution of 0.4 gm gliotoxin from *P. janseni* in 100 ml chloroform $[\alpha]_D^{17.5}$ was -248°, and for a solution of 0.65 mgm gliotoxin from *T. viride* in 100 ml chloroform $[\alpha]_D^{19}$ was -243°.

The absorption spectra in the ultra-violet have been studied by Mr F. M. Page and Dr W. C. Price. Solutions of the two specimens give the same absorption curve.

Biological properties of gliotoxin from *P. janseni* and from *T. viride* are identical, so it is concluded that the observed differences in size and arrangement of the crystals were in all probability due to traces of impurity in one or other of the samples.

We have found gliotoxin to be highly toxic to mycorrhizal fungi. Various concentrations of gliotoxin were included in malt-extract agar (pH 5.2) by addition of Seitz-filtered aqueous solutions of gliotoxin to tubed agar medium at 40° C, followed

by rapid cooling to avoid decomposition of the gliotoxin. The degree of growth of a range of mycorrhizal and pseudomycorrhizal fungi on these media, after fourteen days incubation at 25° C, is recorded in Table 2.

++ normal growth, + reduced growth, — no growth

Newman and Norman⁶ have presented strong evidence that the low level of microbiological activity in sub-surface soils is due to the accumulation of antibiotic metabolic products of certain soil organisms. It appears plausible to suppose the toxicity of Wareham soil to mycorrhizal fungi, and its generally low microbiological activity to be due to accumulation of gliotoxin and other antibiotic substances produced by the *Penicillium* spp. dominating its mould flora. It is realized that further investigation will be necessary before final proof of this hypothesis can be offered.

We are much indebted to Dr M. C. Rayner for cultures of mycorrhizal and other fungi.

Influence of pH and Salts on the Solubility of Calcium Oxalate

It has been observed that ingestion of soluble oxalates aggravates the condition of oxaluria. Barrett¹ has shown that oxalate absorption is reduced or even inhibited when milk or a soluble calcium

salt is taken simultaneously. He explains this as an immobilization of the oxalate as calcium oxalate, which is almost insoluble at the pH obtaining in the intestine. Whether intestinal absorption of calcium oxalate is influenced by other ions has been little investigated. Fiske and Logan² have noted the effect of magnesium, phosphate and sulphate on the solubility of calcium oxalate but have not presented quantitative data. We have investigated quantitatively the effects of acetate, borate and

TABLE 3 M/5 BORIC ACID, M/5 SODIUM HYDROXIDE

phosphate ions at various pH values on the solubility of calcium oxalate.

The general principle adopted was the addition of various amounts of M/5 sodium hydroxide to a fixed amount of M/5 acid and dilution with water to a fixed volume. For example, to 50 ml M/5 phosphoric acid 5, 10, 15, etc., ml M/5 sodium hydroxide were added and the total volume made up to 200 ml in all cases. Excess powdered calcium oxalate was added and the mixture kept at 38° C. After determining the pH with a glass electrode potentiometer the mixtures were filtered and the filtrates titrated with potassium permanganate. The titration values given in the accompanying tables are in ml N/100 potassium permanganate per 100 ml filtrate.

From our results it appears that the solubility of calcium oxalate is little affected by acetate ions between pH values 2.72–7.26, and borate ions between pH values 8.40–10.56. In the presence of phosphate, however, the solubility decreases between pH 1.56 and pH 6.16, then increases gradually up to pH 8.2 and thereafter very steeply. Moreover the minimum solubility of calcium oxalate has a higher value in the presence of phosphate than of acetates.

In the pH range 6.5–8.0 reported to be found normally in the intestine, the solubility of calcium oxalate and therefore absorption of oxalate ions arising from calcium oxalate is small even in the presence of phosphates of the food. Should conditions arise leading to a greater alkalinity than pH 8.0, say, 8.0–8.4, in the intestine, we infer from our results that absorption of oxalates arising from calcium oxalate should be considerable in the presence of phosphates. That this increase in solubility is due to replacement of oxalate by phosphate is borne out by phosphate estimations on filtrates corresponding to pH 7.58 and pH 10.40 (Table 1). Although the initial concentration of phosphate in the two buffers was identical, the final values were in the ratio, phosphate (pH 7.58) : phosphate (pH 10.40) = 80 : 1.

A similar displacement was observed on the surface of a specimen of urinary oxalate stone when it was placed for a day in a Sorensen buffer of pH 8.0.

Particle Shape

MR E J W WHITTAKER has directed attention¹ to the frequent use of the term 'needle-shaped' in chemical literature as a loose description of certain crystal shapes, and proposes a method of calculating an 'acicularity coefficient' to make this description more precise. Such a coefficient, however, would be characteristic not of the substance, but only of a particular batch of it formed under conditions which give rise to the particular 'habit'.

The bare description, 'needle-shaped', occurs frequently when a complete crystallographic description seems desirable. Its use is sometimes a confession of failure, the crystals being so thin that the observer cannot discover the exact nature of the terminations. Sometimes one feels that the term merely expresses lack of interest in the crystallographic details.

The measurements which Mr Whittaker suggests (three on each crystal) would involve a considerable amount of labour. If one's purpose is to describe a substance, it would seem better to expend the effort in an attempt to determine a few crystallographic constants which would be truly characteristic. If, on the other hand, one is interested in chemical reactivity or physical properties, a study of 'habit' may be valuable. In this case, however, the equidimensional particle (for example, cube or sphere) should be regarded as one end-point in the scale, as in Wadell's sphericity number. Wadell² expresses the sphericity by the fraction d_n/D_s , where d_n is the diameter of the sphere of the same volume as the particle and D_s is the diameter of the circumscribing sphere. A slight modification of his test may quite easily be applied to rectangular parallelepipeds, and if the sides are $a \geq b \geq c$ the degree to which the particle approaches the equidimensional habit (the cube) is clearly $\sqrt[3]{abc/a}$, the perfect cube being represented by unity. The cube possesses no relative elongation along its axes, and one mode of establishing a scale in which the cube has relative elongation of 0 is to define the elongation as $1 - \sqrt[3]{abc/a}$. Some may find it easier to comprehend these assessments if the values are all multiplied by 100, so that one can speak of a cube as being 100 per cent equidimensional, and an infinitely long needle as being 100 per cent acicular.

A more detailed classification of shapes by Zingg³ takes ratio into consideration in a somewhat similar manner to that used by Mr Whittaker, but Zingg's method leads to the recognition of tendencies towards our habits: spherical (for he approaches it from the sedimentary petrographer's point of view), disk-shaped, rod like and bladed.

It should be borne in mind that with microscopic articles, the measurement of two dimensions may be all that is practicable, and shape assessments based on this limited data may be better than no data at all.⁴

FRANK SMITHSON

British Potteries Research
Association,
Penkhull,
Stoke-on-Trent

Nature, 155, 331 (1945)

Wadell, H., *Pan-Amer Geol*, 61, 187 (1934)

Zingg, T., *Schweiz Min W Pet Mitt*, 15, 39 (1935).

Wadell, H., *J Geol*, 43, 250 (1935)

Rittenhouse, G., *J Sed Petrol*, 13, 79 (1943)

THE coefficients proposed by Mr E J W. Whittaker¹ for expressing shapes of rectangular parallelepipeds are not, in my opinion, quite satisfactory. The acicularity coefficient (ac/b^2) does not really express true acicularity, because the term 'acicular' means 'needle-shaped' and is commonly applied to elongated crystals with a cross-section approaching a regular polygon. The term 'acicular' cannot, strictly speaking, be applied to elongated tabular crystals, which are usually referred to as 'laths', if short, and 'blades', if long. Again, the isoproportionality coefficient ($a \cdot b$ or $b \cdot c$) does not express any significant shape, because it is based on two dimensions only.

Various coefficients can be devised for expressing the habit of crystals, but I think that the following coefficients are better suited to express the characteristic shape of a rectangular parallelepipedon ($a \geq b \geq c$)

$$1 \text{ Elongation } E = \frac{a^2 - b^2}{bc}$$

$$2. \text{ Tabularity } T = \frac{ab^2 - ac^2}{bc^2}$$

For a cube, both these coefficients are equal to zero

S I TOMKEIEFF

King's College,
Newcastle-upon-Tyne

¹ Nature, 155, 331 (1945)

MR S I TOMKEIEFF's criticisms of the coefficients I have proposed for expressing particle shape are based on two points: the term 'acicularity' applied to the coefficient ac/b^2 , and the use of $a \cdot b$ or $b \cdot c$ as the second shape parameter. With regard to the definition of acicularity, I would point out that my use of this term is an extension of its common meaning, so that it may be applied in a generalized sense to figures with three unequal principal dimensions. This extension is quite analogous to the extension of the terms positive and negative as applied to the indicatrix of biaxial crystals in crystal optics, these terms being derived from their use in describing the indicatrix of uniaxial crystals. Also, although my isoproportionality coefficient is not an explicit function of all three dimensions, it is not independent of any of their values owing to its definition as $a \cdot b$, or $b \cdot c$, whichever is the smaller, and it does, in combination with the acicularity coefficient, uniquely express any shape. Although there is a loss in mathematical rigour here, there is a great gain in simplicity.

Satisfactory coefficients for describing particle shape must satisfy the two mathematical criteria

(1) The coefficients must be homogeneous functions of a , b and c . (2) They must be independent.

They should also satisfy, so far as possible, the following four conditions: (3) The coefficients applicable to a complex shape should analyse that shape into two variables which are readily separated subjectively in the impression given by the complex shape. (4) Their numerical values should vary along a series of shapes in accordance with subjective estimates of the changes occurring from one shape to another. (5) The coefficients should be as easily calculable as possible from the values of a , b and c . (This is of considerable practical importance if a large number of particles is being measured.)

(6) The coefficients should possess whatever other properties may be required for the work in connexion with which they are to be used.

Elongation and tabularity probably satisfy condition (3) better than do the acicularity and isoproportionality coefficients. But subjective impressions are much less sensitive to slight changes of shape than are the numerical values of E and T , and the calculation of these coefficients involves a considerably greater number of operations than is required for the acicularity and isoproportionality coefficients. With regard to condition (6), the two systems are probably suited to different purposes. Thus on my system a mixture of tabular square prisms and elongated ones would always give mean coefficients corresponding to a square prism (or to a cube if the values were appropriately distributed), whereas on Mr Tomkieleff's system it would not.

Chemistry at the Older Universities

In an article in *Nature* of February 10 on "Chemistry at the Older Universities of Britain during the Eighteenth Century", Dr Archibald Clow repeats a number of assertions of a highly flattering character, which have been made from time to time regarding John Mayow, by Beddoes, Yeats, Gotch, Gunther and others, statements which it is surely time to eliminate from the history of science. Dr. Clow says that Mayow's "De Sal-nitro et Spiritu nitro-aereo heralded the later discovery of oxygen", and he quotes, apparently with approval, Gunther's view that Mayow was the "greatest chemist whom Oxford ever produced". Also he says that "Mayow was not an associate of Boyle, indeed they seem to have been mutually unaware of each other's work, and Mayow's contributions remained hidden for many years".

In an article published some time ago entitled "John Mayow in Contemporary Setting"¹, I pointed out that these views—as, well as many others held regarding Mayow—are very erroneous, and that Mayow's work, far from being independent of Boyle's, was merely a pale reflexion from it. Mayow, in fact, mentions Boyle fairly often, and states that some of his experiments were similar to those of Boyle. Part of his endeavour was to show that what we call nitric oxide obeyed Boyle's Law, and although here he does not mention Boyle he very probably thought the connexion to be so obvious as not to require it. That Mayow's work was not hidden at all is shown by the fact that it received extensive review in the *Phil Trans* at the time of its publication.

On the other hand, that Boyle was aware of Mayow seems to be clearly indicated by the fact that Oldenburg, in a letter dated July 10, 1674, writing to Boyle, says "I hear some very learned and knowing men speak very slightly of the *quinque Tractatus* of J M, and a particular friend of yours and mine told me yesterday, that as far as he had read him, he would shew to any impartial and considering man more errors than one in every page"². All who have really studied Mayow's work are pretty certain to agree with these "learned and knowing

men". It is time that our perspective regarding Mayow was finally and definitely readjusted.

T S PATTERSON

University of Glasgow

¹ *Iris*, 15, 47, 504 (1931)

² Boyle's "Works", 5, 395b (1744)

It has been very kindly pointed out to me by Dr K. R. Webb, of Southampton, that I have done less than justice to Cambridge chemistry by omitting to mention that it was I Milner (1750–1820) who, although Jacksonian professor of natural philosophy and not a chemist *per se*, observed in 1788 the ammonia passed over heated manganese dioxide converted into red fumes which dissolve in water to form nitric acid. This oxidation of ammonia effected catalytically by atmospheric oxygen is the basis of the modern commercial method of preparing nitric acid. Both Milner and his successor, F J E Wollaston (1762–1823), taught chemistry and published plans of their courses.

Other minor points are 'Robinson', p 161, col 1, line 38, should read 'Robison', 'Vagani' should read 'Vigani' throughout, the intrusive comma between Cullen and went, p 160, col 2, line 41, should be deleted, the first of R Watson's Essays appeared three years earlier than stated, finally, although R T Gunther in "Early Science in Cambridge" (p 225) gives the date 1741, apparently Mickleburg (or Mickleborough) held office until 1756.

On the other hand, as far as Oxford is concerned following the long line of historians from Beddoes to Gunther I credited John Mayow with being one of the great luminaries of early Oxford chemistry. That this is not so has been discussed by Prof T S Patterson, and all chemists interested in the early history of their subject should refer to his masterly analysis referred to above.

Exygnopia

From time to time I have experienced, immediately upon awakening from sleep (ἐξυπνοϛ), the ability to see with illumination below the threshold for scotopic vision. This power of seeing in the dark, which is transient, is quite different from scotopic (twilight) vision: the colour red can be distinguished, and the field of vision is small. I think that the portion of the retina employed is the *macula lutea*, a part which is generally regarded as being night-blind. That the illumination was really below the threshold for scotopic vision is confirmed by my wife who, on at least two of the several occasions, observed that the room (which was 'blacked-out') was pitch-dark.

The phenomenon appears to me to be an interesting survival of a faculty which must formerly have been of considerable value to man, a faculty analogous to that of pricking up the ears, which some of us doubtless the less highly civilized—still retain.

RESEARCH ITEMS

Some Interesting New Fishes

GEORGE SPRAGUE MYERS describes two remarkable mute blind fishes and some related forms in his recent work ("Two Extraordinary New Blind Hematognath Fishes from the Rio Negro, representing New Sub-family of Pygididae, with a Re-arrangement of the Genera of the Family, and Illustration of some Previously described Genera and Species from Venezuela and Brazil" *Calif Acad Sci Fourth Series* 23, No 40, Nov 1944). These two blind fishes, *Pygidianops egermanni* (new genus and species) and *Typhobelus ternetzi* (new genus and species), have no cheek spines. *Pygidianops* has no eyes, and *Typhobelus* they are rudimentary. They resemble each other closely but differ sufficiently to warrant a separate genera. They form a series with *Anapteryx anguilla* Myers, described previously in the same locality, rock pools below Sao Gabriel Rapids, Rio Negro Brazil, which possesses eyes and many ways resembles the other two. It is probable that the two blind fishes live buried in the sand. The author is of the opinion that the absence of cheek spines is a primitive feature which relates them to *Nematogenys*, the most primitive pygidid, and that they are probably derived from the Nematomyxinae.

New Genera and Species of New Zealand Collembola

A PAPER by J. T. Salmon of the Dominion Museum, Wellington (*Rec Dom Mus*, 1, 123, 1942-44), describes nine new genera and forty-one new species of *Collembola*. Nine varieties are classed, provisionally, as new sub-species, but the author is of the opinion that these are more probably only colour variations of the species. The paper is the result of an investigation (mainly in the Wellington area) of what is termed "the micro-Collembolan fauna of leaf-mould and soil". Full and systematic descriptions of the genera and species, together with twelve plates (one coloured) containing clearly executed illustrations, make this a valuable reference work.

New African Onychophora

R. A. HOLLIDAY records some interesting observations on the behaviour of peripatids in captivity. Further Notes on Natal Onychophora", *Ann Natal Mus*, 10, Part 3, Dec 28, 1944). These chiefly refer to *Peripatus mosleyi*. Apparently the young are born only towards the end of March and throughout April. The number of young produced by one female is 6-8 in a year, one, or more often two, at a time. The newly born young eats its first moult and then proceeds to fend for itself, the feeding habits being similar to the adult. The insect food is covered with a copious flow of saliva, and it seems that it is probably at least partially liquefied before being ingested. These notes are accompanied by a very beautiful series of photographs.

Schizotrypanum Cruzi

H. Meyer and M. X. Oliveira have published a paper with the title, "Sobre o Desenvolvimento Intracelular do 'Schizotrypanum Cruzi' Em Cultura Tecido Como Meio De Verificacao Da Autonomia Celular" (*Rev Brasil Biol*, 4, No 1), in which it is shown that there is a strict relationship between the life of *Schizotrypanum Cruzi* and the host cell. *Cruzi* continues to develop in the cells until it has exhausted all its nutrient media, and the physio-

logical condition of the cell determines the number of trypanosomes that are formed. From this it may be conjectured that cells in tissue cultures are independent units, because, on the assumption that an inter-cellular connexion exists, it would be possible for the parasite to migrate to an adjacent cell from which it could derive nourishment. A number of experiments proved, however, that this did not occur. Adjacent cells have the parasite in different stages of development, and so far the investigations have proved that the life-cycle of *S. Cruzi* is always restricted to one cell. The subject is to be dealt with more fully later.

Preferential Segregation in Maize

A. E. LONGLEY (*Genetics*, 30, 100, 1945) shows that in the presence of the knobbed chromosome 10 of maize the genes on other chromosomes which bear knobs sometimes show preferential segregation. Rhoades had already found that genes on knobbed-chromosome 10 segregated in a preferential manner. Longley shows that there is a preferential accumulation of non-homologous knobbed chromosomes in the functional megaspores. There results a preferential disjunction and accumulation of knobbed chromosomes to the functional megaspore. Two genetical results are to be expected and are shown to be occurring: (a) abnormal segregation of genes located near the knobs, (b) false linkage between genes on non-homologous chromosomes. There is little or no evidence of a corresponding behaviour in microsporogenesis.

Low-Temperature Requirements of Fruit Trees

DECIDUOUS fruit trees often fail to show normal spring bud-opening unless during the dormant season they have been exposed to low temperatures for periods which vary with the species and even with the variety. With grapes, C. A. Magoon and I. W. Dix (*Proc Amer Soc Hort Sci*, 42, 407, 1942) find that when the plants are placed in a greenhouse at 60-70° F. after exposure to 45° F., the number of days required for bud-break to occur is inversely related to the number of hours of exposure to the low temperatures. Here as with blueberries (G. M. Darrow, *ibid*, 41, 189, 1942) varietal differences exist and with blueberries the absence of sufficient winter chilling results in unsatisfactory spring growth and, frequently, the subsequent death of the plants. Delayed spring bud-opening, too, is exhibited by insufficiently chilled pecan trees, but C. W. V. Horn (*ibid*, 41, 65, 1942) reports that winter spraying with 2,4-dinitro-6-cyclohexylphenol prevents this delay in spring growth. On one variety (Halbert) that requires only very slight winter chilling, the effect of the winter spraying was only slight.

Energy Relation in Enzyme Reactions

ALTHOUGH on a thermodynamic basis a very large number of reactions may be theoretically possible in a given biological system, the presence of enzymes will result in the selective catalysis of only a limited number of these reactions. In the cell, the prominent processes of hydrolysis and condensation and of oxidation-reduction are accompanied by a variety of other reactions such as amination, deamination, alkylation and so on. Many such reactions are proceeding in the cell continuously and simultaneously. Proteins are constantly being broken down into their constituents and these degradations are balanced by syntheses. The position of this dynamic equilibrium

is determined not only by the thermodynamic potentials but also by the kinetics of the reactions catalysed by the individual enzymes. In "Energy Relationships in Enzyme Reactions" (*Ann New York Acad Sci*, 45, 357, 1944), by J S Fruton, E G Ball, M Bergmann, H M Kalekar, O Meyerhof and C V Smythe, some of these problems, such as the energy-yielding mechanisms favouring peptide bond formation, are discussed.

Aluminium Phosphide

FIVE different compounds of aluminium and phosphorus have been reported at different times, prepared in various ways. W E White and A. H. Bushey (*J Amer Chem Soc*, 66, 1666, 1944) prepared a phosphide by a method depending on passing hydrogen containing phosphorus vapour over an intimate mixture of finely divided aluminium and red phosphorus, and then starting the reaction by heating the mixture. A short, vigorous reaction occurred, and the product was cooled in hydrogen. The product was analysed in different ways and its composition found to be variable. The authors discovered, however, that the X-ray spectra were identical for the principal constituent, and by a visual comparison of the intensities of the aluminium lines on the powder diffraction patterns and a process of correlation with mixtures of aluminium powder and quartz, and by a consideration of the hydrogen liberated by acid, the conclusion was reached that only one compound, AlP, exists. The highest purity reached was 94 per cent AlP. The compound is remarkably stable to heat, but is, of course, decomposed by moisture with evolution of phosphine.

Average Magnetomotive Force Expended on Tapered Teeth

A PAPER by O I Butler (*J Inst Elec Eng.*, 92, Pt 2, No 25, Feb 1945) outlines the theory, method of construction and use of a family of curves allowing a rapid and accurate estimation of the average m m f expended on tapered magnetic teeth of an electrical machine. The parameters used result in less complicated relationships between the variables than with any alternative accurate method, this somewhat simplifies the calculations necessary to obtain the curves for magnetic materials having different B/H characteristics. An analysis is made of the inaccuracy of the simple 'one-third' rule under varying conditions of magnetic loading and tooth profile, and it is shown that the use of this rule can lead to very considerable errors.

Relation of Geomagnetism to Solar Activity

A J OL (*Bull Acad Sci URSS, Sér Géog Géophys*, No 6, 359, 1943) presents a new theory of geomagnetic phenomena in their relation to solar activity. This theory, originally suggested by M N Gnevyshev in 1938, attempts to correlate geomagnetic disturbances not with the individual solar phenomena but with the whole process of solar activity manifest in sunspots, solar flares and flocculi as developed in the active regions of the sun. Such a process is called the 'solar impulse'. The statistical study carried out by the author shows how much this theory can be developed and elaborated. It is shown, for example, that geomagnetic phenomena are associated with the phase of the solar impulse which follows its maximum phase. It is suggested that this theory provides a more precise correlation between solar activity and geomagnetism.

Atmospheres of Planetary Satellites

THE 82-in reflector of the McDonald Observatory has recently been used in conjunction with low- and medium-dispersion spectrographs to study the atmospheres of Pluto and of the largest ten satellites of the solar system. In his preliminary report on the results (*Astrophys J*, 100, 378, 1944), G P Kuiper reproduces a series of interesting spectrograms of the satellites and their primaries in the photographic visual and infra-red regions of the spectrum. On Titan, sixth and largest satellite of Saturn, is found to have an atmosphere of sufficient prominence to be detected, though Triton, Neptune's satellite, and Pluto are to be studied further. The composition of Titan's atmosphere is similar to that of Saturn though the optical thickness is somewhat less. The methane absorption bands at 6190 Å and 7260 Å show up well; and the ammonia band at 6400 Å, suspected on microphotometer tracings, though confirmatory plates will be needed to establish its presence. The presence of molecules rich in hydrogen on a body so small as Titan is rather surprising. Stability during astronomical periods is not possible for hydrogen itself under present conditions on Titan though methane and ammonia are retained. But a substantial increase in temperature, say, by 100° would result in rapid dissipation even of the present constituents. Consequently, the present atmosphere must have been acquired since Titan had the high surface temperature which current theory demands for all bodies of the solar system. Similar, though less compelling, considerations follow for Mars, Venus and the earth, in all of which the atmosphere must have escaped from the crust after the latter had cooled.

Variability of γ Cassiopeiae

D L EDWARDS, Norman Lockyer Observatory, Exmouth, in a paper 'Changes in γ Cassiopeiae During the Past Hundred Years' (*Mon Not Roy Astro Soc*, 104, 283, 1945) discusses all available observations of this star since 1830 with the object of detecting any variations of magnitude or spectrum before the previous outburst. The first suggestion of variability in γ Cassiopeiae was made by W. R. Birt (*Mon Not Roy Astro Soc*, 2, 79), and although he referred again to his suspicions twenty-six years later, does not appear to have followed the matter up. As a result of his collection of data, Edwards concludes that even before the recent outburst this star was subject to frequent variations in spectrum and magnitude, although these changes were small in comparison with those observed after 1933. In spite of the fact that the changes were frequently very small, they have been supported by independent evidence, often from different observers, and in several cases they are sufficiently large to leave little doubt as to their reality without any other evidence. The suspected changes occur at dates which fall into regular periodic series, and the best fit was found by trial and error, to be given by a double maximum with a separation of 4.30 years, recurring at intervals of 10.67 years. Hence the maximum occurred regularly at intervals of 4.30 and 6.37 years alternately, and these figures were used, with the well-determined date of 1937.3 as starting point, to determine computed dates of maxima. The observations fit very closely into the scheme with the exception of the 1934.6 outburst, and it is suggested that this was due to some exceptional cause.

NATURAL HISTORY OF SCRUB TYPHUS*

THE work of the last ten years on diseases of the typhus group has permitted us to understand certain sides of them much more clearly. It is now known that there is one disease of this group widely read in eastern Asia, transmitted from rodents to man by what we should call harvest mites. It should be known as 'scrub typhus' or alternatively as 'mite-borne typhus'. No good general account of it, particularly from the entomological side, is available in print. The disease is of considerable importance in the British Empire.

The natural history of the disease is complex, and may be best to approach it by setting down what is known about the so-called 'harvesters' of Britain and northern Europe. They are the larvae of *Trombicula autumnalis*, the so-called 'chiggers' of North America, are closely related. These larvae, which are fraction of a millimetre long, attach themselves to the skin of rodents, man, birds, etc., and hold on for several days. They drop into the soil, moult to become a nymph, moult again to become an adult and the female then lays eggs. Our knowledge of the life-history in the soil is fragmentary, but it seems to be established that the nymph and adult are vegetarians or that they feed on decomposing organic material. It seems that there is only one species in Britain, and it is probable that there is only one generation in the year. It is known that the rabbit and the bank vole are important hosts of the larvae. The bank vole, larvae are common in late summer and autumn and after that diminish through the winter, to fall to a minimum in June. The species occurring in Britain seems to be localized to light soils, particularly those which are chalky, and the distribution is often extremely patchy. It seems probable that, by applying methods worked out for problems of soil entomology, much might be learned about the biology of this animal.

In attaching itself to the mammal, the larval *ombicula* ejects a digestive juice which causes an area of hyaline degeneration. This often takes the form of a sharply defined column, vertical to the skin. Nothing is felt at the time when the larva is puncturing the skin, but some hours later irritation develops in some, but not all, human beings. The irritation may be quite serious, particularly to troops living in the field.

In south-east Asia there are many genera and species of Trombiculid mites, and the larvae of a considerable number of them attack man. Rodents are mainly important hosts, and the natural history of scrub typhus is very complex because of the variety of rodents in this part of the world.

The larvae are important because they transmit an infectious agent producing the disease, we call scrub typhus. The earlier work was mostly Japanese. It showed that the larva of *Trombicula akamushi* feeds normally on voles (*Microtus*) on alluvial soils, transmits infection from vole to vole or vole to man. As the mite only feeds on a mammal once in its life-history, the infection must be hereditary, and the virus has actually been recovered from wild adult voles. A similar or identical infection, always transmitted by larvae of *Trombicula*, is known or believed to occur in the great triangle bounded by Japan, New

Guinea and northern Queensland, Ceylon and the Maldives. Within this great area the disease may occur under exceedingly different environmental conditions, for example, in equatorial forest, or in grassland, or on barren islets and atolls.

In man the disease is generally serious. There is a small ulcer at the site of attachment of the larval mite, high fever and a considerable mortality. The disease is widely distributed over the area of south-east Asia, and as men are living and fighting in jungle, it has proved much more common than generally expected. It tends to be highly localized and to produce occasional outbreaks with a very variable but serious death-rate.

CONFERENCE ON X-RAY ANALYSIS*

THE second Annual Conference of the X-Ray Analysis Group of the Institute of Physics, and the fourth Conference on X-Rays in Industry which the Institute has arranged, was held in London at the Royal Institution during April 12-13. The Conference was an open one, and the attendance was about two hundred and fifty. The chairman, Sir Lawrence Bragg, opened by thanking the Royal Institution for the use of its premises, and welcomed scientific visitors from the Continent, who for the first time were able to be present at the Conference. Speaking of the X-Ray Analysis Group, Sir Lawrence reported briefly on its work during the past year. It now has 187 members, and in addition to its annual conference it held a meeting in Leeds last November on the performance of X-ray tubes. The committee has also produced recommendations for the design and dimensions of a standard powder camera, and has in hand the revision and reproduction of Beevers-Lipson strips for Fourier analysis. It was hoped that the Group might sponsor the publication of a journal for papers on the atomic structure of matter and allied subjects. The chairman, secretary-treasurer, and ten members of committee of the Group were declared elected, in the absence of further nominations. A warm vote of thanks was made to Dr Lipson for his work for the Group since its formation, his place as honorary secretary-treasurer is to be taken by Mr F A Bannister (Minerals Department, Natural History Museum, Cromwell Road, London, S W 7).

Absolute Values of X-Ray Wave-Lengths

At the Conference in 1943, the question of correcting X-ray wave-lengths, which were known to be in error by about 0.2 per cent, was left until the conversion factor might be more accurately known and international agreement might be reached as to its value. As these conditions are now at least partially fulfilled, the meeting considered further steps to be taken. Dr Lipson said that there are three possibilities to recommend immediately a value of the conversion factor, to leave the determination of the conversion factor to Prof M Siegbahn and the Americans who have worked on it, or to continue to use the old wave-lengths and await further developments. Of these he prefers the first.

* Substance of a Friday discourse at the Royal Institution delivered by Prof F A Buxton, F.R.S., on April 27.

* Report prepared by Audrey M B Parker, A R Stokes and A J C Wilson.

Dr W A Wooster said that it would be undiplomatic to do anything further until other men of science on the Continent can be consulted, but Dr W H Taylor considers that Prof Siegbahn is the only authority who need be approached. Dr Lipson said that the agreement between Prof Siegbahn's value of 1.00201 and the Americans' value of 1.00203 for the conversion factor is extremely good, and pointed out that an accuracy better than 1 part in 10^6 could scarcely be expected in view of the breadths of X-ray emission spectra. It was agreed after some discussion that the chairman should ask Prof Siegbahn and Dr R T Birge and Prof B E Warren to reach agreement on the best value of the conversion factor, after which the American and British X-Ray Analysis Groups should prepare new sets of tables of wave-lengths and crystal lattice parameters embodying the corrected values. For the time being it was agreed to use 'kX' instead of the (incorrect) 'A' as the abbreviation for 1,000 X-units.

Proposed Publication of a Journal

Sir Lawrence Bragg reported to the Conference on the discussions of a sub-committee on publication. There is at present no journal dealing satisfactorily with the interests of the Group, and papers on crystallographic subjects appear in nearly sixty different periodicals. The committee is satisfied that there are enough British papers yearly to make possible the publication of a quarterly journal. The scope of the journal would be determined by the material investigated, not the methods used, that is, it would cover structure of matter, not diffraction. The American Society for X-Ray and Electron Diffraction is discussing a similar project, and it might be possible to co-operate with them. The possibility of co-operating with Continental workers is also under consideration.

The Conference expressed its general approval of a new journal, and authorized the committee of the Group to continue with the project.

X-Ray Diffraction Technique

Two sessions for the presentation of scientific papers were held on each day. During the first morning session, a number of new and improved methods of use of X-ray diffraction were described. These were concerned more with techniques than with fundamentals, and embodied a large number of useful ideas for experimental work. Dr A Guinier described the use of convergent and practically monochromatic beams of X-rays obtained by reflexion from bent quartz crystals ground to a suitable curvature, and showed how very clear diffraction photographs can be obtained with short exposures. Mrs Nora Wooster spoke about the use of the Weissenberg goniometer for determination of the orientation of diamonds and the examination of the variation of perfection of crystal surfaces. There followed papers by Dr I MacArthur on the measurement of long spacings in protein fibres, including special precautions needed when spacings are of the order of 500 Å, by Mr J B Nelson on extrapolation methods for the elimination of errors in lattice parameter measurements, by Miss A M B Parker on small-radius cameras for rapid selection of single crystals and determination of their orientation, and by Dr W Wrazej on the examination of tempered martensite.

Dr. A J C Wilson reported on the progress of the

index of powder photographs which was started under the Institute's auspices soon after the 1942 Conference in order to supplement the index produced by the American Society for Testing Materials. He said that as a result of a search through papers published during 1925-39, and of the response by the British Museum and many industrial laboratories to a general appeal, the X-ray data for 1,200 more substances had been collected and sent to America for publication by the American Society for Testing Materials. The supplement to the Index would soon be available and annual supplements are to be issued.

Laboratory Equipment

The afternoon session on April 12 was devoted to a discussion of laboratory equipment. The outstanding feature was a demand for the preparation of standard specifications for many types of instruments such as high-temperature, long-spacing and other X-ray cameras, microphotometers, X-ray tubes, etc. Standard specifications for a powder camera have already been prepared by the X-ray Analysis Group Committee. It is recognized that such standard equipment, if made, will not be final, and work will still have to be able to improvise.

Dr R. F. Hanstock described an industrial laboratory equipped primarily for the determination of residual stresses in fabricated aluminium alloy. Special devices for mounting specimens up to 3 in diameter are provided. The specimen-to-film distance is obtained by smearing vacuum-annealed silver powder on the specimen surface, and it is estimated that the stress is obtained to an accuracy of better than 1 ton/sq in. Geiger counters have been found satisfactory for recording positions of X-ray diffraction maxima.

Mr H S Peiser began his talk by enumerating the types of problem which are dealt with in industrial crystallographic laboratories, namely (1) identification, (2) semi-quantitative analysis, (3) molecular weight and shape, (4) crystal structure, (5) texture. Some possible modifications to Astbury's design of a rotating anode tube³ were mentioned, and some details of a home-made gas tube given. It can be shown that a hot-cathode demountable tube gives a slightly more intense beam than the cold-cathode tube, though it is less efficient, and gives more white radiation. He stressed that reasonable care should be taken to safeguard the health of X-ray workers.⁴

Dr W A Wooster discussed some methods other than those of X-ray diffraction which are of use in the study of crystals. Information leading to a determination of symmetry class can be obtained from (1) interfacial angles, (2) etch figures, (3) refractive indices, (4) optical anisotropy, (5) piezo- and pyroelectric phenomena. The flotation method for density measurement was mentioned, as was also the determination of molecular orientation from measurement of variation of diamagnetic susceptibility with direction. He described also two methods of measuring peak voltage, one using the minimum wave-length, and the other a potential divider and cathode-ray oscillograph.

Interpretation by Optical Principles

Both sessions on April 13 were devoted to a discussion of the interpretation of X-ray diffraction means of optical principles. The four main contributions were from Sir Lawrence Bragg, Dr H Lips

Mr G B Hey and Prof J M Robertson Sir Lawrence Bragg summarized his paper as "a little of the history and some elementary book-work". He outlined the development of Fourier methods from the first tentative suggestion made by his father⁵ in 1915 to an actual synthesis by Havighurst⁶ in 1925. The book-work was an elementary treatment of Fourier synthesis⁷ and of the Patterson method, to provide a basis for the practical applications following in other papers. He concluded by describing how Fourier summations can be done optically, thus obviating tedious calculations⁸.

Dr Lipson then described some successful applications of Fourier methods. The fundamental difficulty is to obtain the signs (or the relative phases) of the structure amplitudes. This difficulty can be overcome if the structure contains a heavy atom (copper phosphate pentahydrate⁹, phthalocyanine¹⁰), or forms part of an isomorphous series (the alums¹¹), or if the distance between the constituent molecules can be determined suitably (horse methæmoglobin¹²).

In the afternoon, Mr Hey presented a paper by Mr L J Comrie and himself on methods of calculation. The most important requirements are efficiency and ease of checking. The methods developed by crystallographers are in general efficient, but little attention has been paid to checking. Repeating the calculation is a slow and uncertain check. Two safer methods are differencing and cross-summation, and Mr Hey gave details of their application. He concluded by suggesting modifications making the methods more suitable for use by professional computer not expert in crystallography, and describing the least-squares method of refining approximate structures¹³.

Prof Robertson then spoke on the significance of the results obtained by Fourier syntheses. It is theoretically possible for two structures to give identical diffraction patterns¹⁴, and therefore structures should be tested by all other available methods before being finally accepted as true. A check on the correctness of structures is the comparison of interatomic distances found by X-ray analysis with those found by other methods. Such comparisons of carbon-carbon distances indicate that an accuracy of about 0.2 Å is attainable in fixing atomic positions. He concluded by describing the structure of coronene, and mentioning some theoretical implications of the variations found in the carbon-carbon bond-length. A lively discussion followed each of these papers. It is hoped to publish a fuller account of the papers and the discussion in the *Journal of Scientific Instruments*.

Future of X-Ray Analysis

An extremely interesting and inspiring talk on the future of X-ray analysis in the form of an evening lecture was given on April 12 by Prof J D Bernal. He spoke first of the advances which may be expected to take place in fundamental studies when the war-time interruption comes to an end. All basic structure types are now well established, and lines of research will branch out in one direction towards more complicated structures, largely of biological interest, and another towards the elucidation of imperfect crystal structures.

Tools essential to these studies, such as extremely efficient X-ray tubes, and calculating devices of great intricacy, will almost certainly be developed as a result of advances in other fields in physics.

A far greater part will be played by the ever-

increasing use of X-rays as an auxiliary tool in scientific research in other fields. Such use of X-rays has gone ahead during the War, as can be seen from the great success of the Institute of Physics meetings, and the Cambridge Summer School. In order that this research tool should be of the greatest possible use, it must be combined with other techniques such as spectroscopy and microscopy including the electron microscope. A considerable number of research and training schools will be required if there is to be available a sufficient number of trained X-ray crystallographers. In order that this branch of science as a whole shall continue to advance, the connexion between the theoretical and applied fields must always remain as close as, or closer than, it is to-day.

Prof Bernal dealt also with the problem of centralization of publication, and with international co-operation.

Exhibition

In addition to the discussion, an exhibition of X-ray photographs, apparatus and new books of interest to crystallographers was arranged. Several makes of powder cameras and single-crystal rotation and oscillation cameras were on show. There was an ionization spectrometer and a two-crystal moving-film goniometer for the determination of absolute intensities. A back-reflexion camera was exhibited in which the film can be rotated on a ball-race instead of using the collimator itself as a bearing. A new design of goniometer head gives a very wide range of angular adjustment, and can be easily transferred from one suitably fitted camera to another.

A machine for calculating structure factors for one atom was demonstrated, and it was suggested that with a series of these machines it would be possible to calculate structure factors for up to fifteen atoms per unit cell. A very elegant bent-quartz monochromator was shown, with which a relatively very intense convergent crystal-reflected beam is obtained. There was also a demonstration of quartz crystals, and the manner in which they are cut for use in piezo-electric oscillators. Of particular interest to those who wish to make structure models was a special jig for drilling wooden balls, and a new form of clip for holding them securely together. The new books included "The Structure of Metals" by C S Barrett (McGraw-Hill), "X-Ray Crystallography" by M J Buerger (Wiley), and an "Introduction to X-Ray Metallography" by A Taylor (Chapman and Hall, in the press). There were also photo-lithoprint reproductions of some books published in Germany, including "Röntgenstrahl-Interferenzen" by M von Laue and "Internationale Tabellen zur Bestimmung von Kristallstrukturen".

SPIN IN THE UNIVERSE

SIR EDMUND WHITTAKER discussed "The Spin of the Universe" in his presidential address to the Royal Society of Edinburgh at the annual statutory meeting held on October 23, 1944 (Year Book of the Royal Society of Edinburgh, 1945).

Starting with Earl Rosse's discoveries of spiral nebulae, the first of which was *M* 51 (although examined previously by several astronomers the much greater resolving power used by Lord Rosse showed its spiral character for the first time), Whittaker proceeds to examine the cosmological significance of rotation and spin characteristics of the spiral nebulae. He refers to the theory propounded by H. Alfvén (*Ark Mat, Astr, och Fys*, 28 A, No 6, 1942), which accounts for the angular momentum possessed by the planets of the solar system (a short outline of this theory appeared in *Nature*, 150, 405, Oct 3, 1942, and 152, 721, Dec 18, 1943). Alfvén's theory would apply to the stars as well as to the sun, and would lead us to assume that a star is generally accompanied by a family of planets—a view corroborated by recent discoveries of planets associated with other stars. His theory shows how spin can be acquired by material bodies under the action of electric and magnetic fields, or, in other words, spin can be transferred from ether to matter, and hence it is natural to inquire whether anything is known about spin or angular momentum in the ether.

Since the discovery of the theory of relativity, the ether has been discarded except as the name of an invisible transmitter of actions at a distance, and the ether theories have been replaced by the new science of atomic physics. How has the change, in which the fundamental entities are elementary wave-particles or corporundals of certain kinds, affected our conception of invisible spin? Within the last two decades it has been found that each of these elementary particles possesses a certain definite quantity of spin, and this is of great importance in determining the behaviour of the particle. A short description of *quantum numbers* is followed by an account of the discovery in 1925 that a third quantum number is required to describe an electronic level, a discovery which immediately led to the question, "To what physical character of the atom does this new third quantum number correspond?" Reasons were soon forthcoming to suggest that this third number corresponded to the total spin of the whole atom, just as the second quantum number represented the angular momentum or spin of the orbital motion of the electron, and it was shown that it was not the spin of the nucleus but of the electron which took place.

A study of the Zeeman effect led to the conclusion that the angular momentum or spin of the electron is $\frac{1}{2}h$, where h is Planck's constant of action divided by 2π , and that the electron has a certain fixed magnetic moment associated with the spin. It is impossible to verify the spin and magnetic moment by direct observation, owing to the uncertainty principle, and the phenomenon of electron-spin belongs to quantum theory, for which reason it possesses peculiarities not met with in classical dynamics. It is a quantum-mechanical entity, and when we speak of its component in the direction of the *z*-axis, say, the only meaning attached to the statement is that there is a certain probability that the axis of spin will be parallel to the *z*-axis and the spin-component of amount $\frac{1}{2}h$, and also the probability that the axis of spin will be antiparallel to the *z*-axis, the spin

component being now $-\frac{1}{2}h$. It has been found that each of the other elementary particles also possesses a definite amount of spin, the proton, the neutron and the positron can each have the same spin as the electron, $\frac{1}{2}h$, while the photon or light corpuscle has the spin h , and the spin of the meson may have either of the values 0 or h .

Whittaker refers to the important part that the spin of the elementary particle plays in chemical combination and to its influence on what is called the statistical behaviour of the elementary particles, and deals briefly with the Maxwellian statistics, the Fermi statistics, and the Bose statistics, generally recognized under the composite titles, Maxwell-Boltzmann, Fermi-Dirac and Bose-Einstein, but it is impossible in a limited space to deal with every feature of the address. One important matter may be mentioned. The correlation between the particle and the wave properties of the elementary particles has been long known, so far as concerns energy, momentum and velocity, and the question arises, "What feature of the waves is to be interpreted as spin?" Sir Charles Darwin discovered the true solution in 1927, and concluded that the wave-aspect of spin was simply the capacity to exist in different states possessing the same energy and momentum, analogous to differently polarized waves of light. In 1928 Dirac found the wave equation of the electron in a form which was invariant under all the transformations associated with the principle of relativity, and spin appears to be a consequence of the symmetry of the cosmos with respect to space and time. The concept of spin thus emerged in a new light, it had originated in atomic physics, and it was now lifted into a new context, that of relativity theory.

Relativists had directed their attention for many years to the remarkable difference existing, as regards relativity, between motions of translation and of rotation. According to the principle of relativity, it is impossible by observational means to detect uniform motion of translation which occurs wholly within the system, but the case is quite different as regards rotation. We can speak of velocities of rotation in an absolute manner, without specifying the framework with respect to which the angular displacement takes place. Certain problems in the relativity theory of spin arise, to which reference is made, and some of these are still controversial. As Whittaker points out, the study of rotation is essentially a cosmic problem, and attempting to solve it we are brought back to the spiral nebulae. It seems probable that their inner regions rotate as if rigidly connected, the linear velocity increasing with the distance, while in the outer parts the linear velocity decreases with increasing distance. Prof. E. A. Milne has proposed an explanation of the rotation of the spiral nebulae as of the possession of spin by most large objects and groups of objects in the universe. He has deduced from his kinematical relativity that the angular momentum of any cosmical system increases proportionally to the time, that is, to what he calls *kinematic time*, which is time as measured by atomic vibrations and radioactive clocks. Hence a spin which was initially small will grow continually greater, and there is therefore nothing surprising in the existence of large accumulations of angular momentum. No theory to explain spin in the universe has yet been generally accepted, but it is reasonable to hope for a solution of this fundamental problem of cosmology in the near future.

MARINE ECOLOGY AND THE FISHERIES

WITH the present two numbers of the *Hull Bulletins of Marine Ecology*, volume 1 is complete*. Of volume 2 four numbers are already published and three are in the press. Prof A C Hardy, editor of these bulletins, in his explanation at the beginning of volume 1 gives an excellent simplified résumé of the whole. Ecology as he defines it "is establishing the relationship between a creature and its surroundings in terms of quantity." He sketches the gradual growth of marine ecology with admirable clarity, its scope, early history, and the beginning of the work at Hull leading to all these researches. This work, planned by himself and successfully carried out, includes his invention of the plankton indicator and, following this, the plankton recorder, both of which have proved to be of real help to the fishery industry. Here a story is told in the simplest terms which is of special interest and importance. It has always been Prof Hardy's aim to bring science and industry together. How successful he has been is shown in the tributes paid to him by the skippers of the vessels which have his apparatus in use.

His explanation proceeds to summarize each bulletin in volume 1. Again, as simply as possible, the contents of each part are explained, with clear diagrammatic illustrations of apparatus and of planktonic organisms. This is an excellent method of introducing the work to non-specialists.

No 6, concerned with the main plankton survey, deals with the monthly changes in the zooplankton other than Copepoda and young fish as shown by the plankton recorder. Here the seasonal changes are much in evidence, and the distribution of *Sagitta*, *Amacina*, *Clione*, Lamellibranch larvæ, *Cladocera*, *Amphipoda*, Decapod larvæ, Echinoderm larvæ and *Oikopleura* is shown in series of monthly charts, while the seasonal fluctuations are compared in time-chart histograms.

These researches have been suspended for the present, but it is hoped that they may be developed in several directions for a long period in the future.

* *Hull Bulletins of Marine Ecology*, edited by Prof A C Hardy and R C E Lucas. Vol 1, pp 1-111, October 1944, 3s. Title Page, Contents Table, List of Personnel, Preface and Explanation. Vol 1, no 6, pp 255-275, Plates cxvii-cxlv. July 1944, 4s. Continuous Plankton Records. The Zooplankton (other than Copepoda and Young fish) in the Southern North Sea, 1932-37, by Dr G T D Henderson and N B Marshall.

THEOLOGY IN AN AGE OF SCIENCE

IN his inaugural lecture at the University of Oxford on November 3, 1944 (Oxford At the Clarendon Press, 2s net), Prof Leonard Hodgson, regius professor of divinity, asked how the voice of theology is to be heard in a scientifically minded age. Must it not inevitably belong to a world of thought alien to the scientific outlook?

Science has been defined by Dr C H Waddington as "the organized attempt to discover how things work as causal systems." This view assumes that all events are explicable in terms of causal systems (or that there are no events lying outside the range of scientific study). In this case, does the fact that psychologists and sociologists are recognized as men

of science mean that all human behaviour can be accounted for on causal grounds? Or that they can study only such aspects of it as are thus causally explicable?

To take the former view is to beg a very large question, to take the latter is to assert that there can be no scientific study of such purposive behaviour as is explicable in terms not of causes but of reasons—a limitation which psychologists and sociologists would reject.

The fact is remarks Prof Hodgson, "we live in a world in which there are two orders of events—those which follow from causes, and those which are done on purpose, for reasons." Thus, if science limits itself strictly to the causal order it can only deal with one part of our experience.

If theology is a science, it would presumably deal with a subject-matter not dissimilar to those of psychology and sociology, that is, events which are done on purpose, for reasons.

Rejecting the traditional idea of revelation as "erroneous and untenable", Prof Hodgson declares that "the divine revelation is not given in the form of propositions conveying a ready-made knowledge, but in events which are divine redemptive acts." These acts, and the evidence for them, it is the business of theology to study, and here lies its claim to be a science.

"Theology is itself one of the sciences—the empirical study of the evidence for certain mighty acts of God in the history of the world."

To be scientific, such studies would have to be wholly unprejudiced. Of course the evidence for some of these events, and these not the least important, is not easy to establish and it is perhaps not justifiable to speak of these events, as Prof Hodgson does, as "a certain sequence of events which, as events, are as observable as any others."

Theology then would appear to be a science in the same sense as history is one. But to divest theology of its philosophical aspects would be to divest it of most of its interest and depth.

RESOLUTION OF EXTRAGALACTIC NEBULÆ

UNLIKE the other nebulae in the local group, the two companions of the Andromeda nebula—M 32 and NGC 205—and the central region of the Andromeda nebula itself, have hitherto defied resolution into stars by the most powerful instruments at the disposal of astronomers. It was therefore supposed that the luminosity of their brightest stars was abnormally low. This conclusion is amply confirmed by the resolution of these objects on plates taken recently on the 100-in telescope (W Baade, *Astrophys J.* 100, 137, 1944).

Some time ago, unexpected signs of incipient resolution on ordinary plates taken under good conditions gave grounds for hoping that further refinements of technique would lead to complete resolution. This has now been achieved by the use of red-sensitive plates behind a filter passing only the region 6300-6700 Å, so as to avoid the strong night-sky emission. Only nights of exceptional definition were used, and only these if the temperature variations were such as to minimize changes of form of the 100-in mirror. The plates were obtained with exposures of the order of four hours, and show that

the hitherto amorphous structure of these galaxies has disintegrated into a great number of faint red stars close to the threshold limit of the plates

This behaviour is quite unlike that of the hitherto resolvable systems, in which the brightest stars are white and are relatively rare Baade believes that the galaxies contain two types of stellar population differing in their Hertzsprung-Russell diagrams. Type I contains *O* and *B* supergiants and open clusters, and is exemplified by the slow-moving stars in the solar neighbourhood, type II, exhibited pure only in early-type nebulae, contains short-period Cepheids and globular clusters. Both types co-exist in our own galaxy.

This new technique for resolving extragalactic nebulae by employing red-sensitive plates in the best observing conditions with the 100-in telescope has also shown that even early-type nebulae can be resolved if their distance does not exceed 300 kiloparsecs. Since this is the distance usually taken to mark the boundary of the 'local group' of galaxies, the criterion of resolvability becomes the test of membership of the local group. This test, applied by Baade (*Astrophys J*, 100, 147, 1944) to NGC 147 and to NGC 185, shows that these inconspicuous companions of the Andromeda nebula are local galaxies best classified as elliptical nebulae of low luminosity and small density gradient. These additions increase the number of recognized members of the local group from eleven to thirteen, and dwarf galaxies now outnumber giants by two to one.

The proportion of elliptical systems is steadily rising as a result of recent discoveries: they now number nearly a half of the known local nebulae. The new data do not support the view that globular clusters and elliptical nebulae lie at opposite ends of a common sequence of stellar agglomerations. The biggest globular clusters are still some ten times smaller in linear dimensions than the smallest elliptical nebulae, and the mean densities of the two systems differ by a factor of the order of fifty.

FORTHCOMING EVENTS

Monday, May 28

BRITISH PSYCHOLOGICAL SOCIETY (INDUSTRIAL SECTION) (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W C 1), at 12.45 p.m.—Prof C A Mace "Industrial Training or Industrial Education?"

Tuesday, May 29

ROYAL COLLEGE OF SURGEONS (Lincoln's Inn Fields, London, W C 2), at 4 p.m.—Prof Arnold Sorsby "Penicillin and Gramicidin in Ophthalmology"

EUGENICS SOCIETY (at Royal Society, Burlington House, London, W 1), at 5 p.m.—Mr Cyril Bibby "Sex Education—Aims, Possibilities and Plans"

TELEVISION SOCIETY (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W C 2), at 6 p.m.—Dr W Sommer "The Human Eye and the Photo-Cell"

Wednesday, May 30

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W C 2), at 1.45 p.m.—Dr Colin G Butler "The Behaviour of Bees when Foraging"

SOCIETY OF CHEMICAL INDUSTRY (PLASTICS GROUP) (at the Royal Institution, Albemarle Street, London, W 1), at 3 p.m.—Mr H V Potter "Leo Hendrik Baekeland: The Story of His Life" (first Baekeland Memorial Lecture)

PHYSICAL SOCIETY (COLOUR GROUP) (at the Royal Photographic Society, 16 Prince's Gate, London, S W 7), at 3.30 p.m.—Mr L C Jesty "Colour Television"

Thursday, May 31

INSTITUTE OF FUEL (at the Institution of Mechanical Engineers, Storey's Gate, St James's Park, London, S W 1), at 10.30 a.m. and 2.30 p.m.—Conference on "Industrial Thermal Insulation" (to be opened by Dr E W Smith, C B E)

ROYAL AERONAUTICAL SOCIETY (at the Institution of Mechanical Engineers, Storey's Gate, St James's Park, London, S W 1), at 6.30 p.m.—Mr T P Wright "Aviation's Place in Civilization" (Thirty-third Wilbur Wright Memorial Lecture)

Friday, June 1

ROYAL INSTITUTION (at 21 Albemarle Street, London, W 1), at 5 p.m.—Prof James Gray, F R S "Migration of Animals"

INSTITUTION OF MECHANICAL ENGINEERS (at Storey's Gate, St James's Park, London, S W 1), at 5.30 p.m.—Exhibition of Film of Engineering Interest

GEOLOGISTS' ASSOCIATION (at the Geological Society of London, Burlington House, Piccadilly, London, W 1), at 6 p.m.—Prof Austin Miller "Some Physical Features of the Dolgelly District"

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned.

LECTURER IN ORGANIC CHEMISTRY at the City of Liverpool Technical College—The Director of Education, 14 Sir Thomas Street, Liverpool 1 (June 1)

LECTURER IN PHYSICS at Loughborough College, Leicestershire—The Registrar (June 7)

TUTOR, and ASSISTANT TUTOR, in the DEPARTMENT OF SOCIAL SCIENCE, London School of Economics and Political Science—Acting Secretary, at the Hostel, Peterhouse, Cambridge (June 8)

LECTURER IN RUBBER TECHNOLOGY at the Northern Polytechnic, Holloway Road, London, N 17—The Clerk (June 13)

DIRECTOR OF RESEARCH at the Institution of Automobile Engineers—Research Department of the Institution, Great West Road, Brentford, Middlesex, marked "Director of Research" (June 16)

ASSISTANT LECTURER IN ANATOMY, London (Royal Free Hospital School of Medicine for Women, Hunter Street, Brunswick Square, London, W C 1—The Warden and Secretary (June 23)

PROFESSOR OF PHYSIOLOGY at King's College of Household and Social Science—The Academic Registrar, University of London, Richmond College, Richmond, Surrey (June 26)

METALLURGIST in Midlands for research work on cemented carbide—The Ministry of Labour and National Service, Central T and S Register, Room 5/17, Sardinia Street, London, W C 2 (quota F 4005 XA) (June 30)

READER IN ENTOMOLOGY in the University of Durham, tenable at King's College, Newcastle-upon-Tyne—The Registrar of King College (June 30)

PROFESSOR OF INDUSTRIAL HEALTH in the University of Durham, tenable at the Medical School, King's College, Newcastle-upon-Tyne—The Registrar of King's College (July 31)

FELLOWSHIP IN ECONOMICS at Balliol College, Oxford—The Master Secretary (Aug 31)

VICE-PRINCIPAL (woman) of Wye College (University of London) with experience in university teaching in science, horticulture, agriculture or economics—The Acting Principal, Wye College, near Ashford, Kent

THE SCIENCE OF HUMAN RELATIONSHIPS

"If civilization is to survive," wrote President Roosevelt in a speech to have been delivered in Washington at the Jefferson Day Dinner on April 12, "we must cultivate the science of human relationships, the ability of all peoples of all kinds to live together and to work together in the same world at peace." That last message shows that President Roosevelt was looking to the San Francisco Conference, of which he was to have been chairman, as a great essay in the science of human relationships, and it may indeed be true that an end to wars will only be in sight when we develop that science and perfect our understanding of human relationships in organizations that satisfy their needs more perfectly. This point of view was well put by Dr J T MacCurdy in "The Structure of Morale", and if there is to be in any true sense a science of peace its basis may be rather the development and application of biology and the social sciences, including psychology, as Prof Anton J Carlson suggested in his address "The Science of Biology and the Future of Man" (see *Science*, 100, 437, 1944), for example, than an approach from the economic side, the scientific study of history or the application of scientific method to disarmament.

This is not to say that the latter may not have their place, but attempts at the scientific study of international relations such as Prof E H Carr set out to give in "The Twenty Years Crisis" have not yet led very far. Indeed, from his latest book*, Prof Carr seems to have abandoned the effort to outline a science of international politics. His study of nationalism is too brief to be more than perfunctory, and roughly half the book is occupied by a discussion of the prospects of internationalism, this, although the scientific approach is abandoned, is highly pertinent to discussions on the Dumbarton Oaks proposals and the proceedings at San Francisco.

Prof Carr's sketch of the rise of nationalism from the sixteenth and seventeenth centuries to its climax between 1914 and 1939 in the totalitarian State attributes the latter to three factors: the socialization of the nation, or the bringing of new social strata into the effective membership of the nation; the nationalization of economic policy, and the geographical extension of nationalism as seen in the increase in the number of nations. That last factor, especially in relation to the principle of self-determination, Prof Carr has already closely analysed in "Conditions of Peace", and his discussion of the prospects of internationalism is no less realistic in the present volume. He challenges and rejects forthright the claim of nationalism to make the nation the sole rightful sovereign repository of political power and the ultimate constituent unit of world organization. He equally challenges the principle of "the sovereign equality of all peace-loving States" of the Moscow Declaration of October 1943, which although embedded in the Dumbarton Oaks proposals is, as was

* Nationalism and After By Prof Edward Hallett Carr. Pp vi+74 (London Macmillan and Co., Ltd., 1945) 3s 6d net

pointed out in the recent debate, by no means consistent with that scheme, apart altogether from the vexed question of the voting formula.

Within its limits, Prof. Carr's little sketch and analysis is a sound contribution to lucid thought about the Dumbarton Oaks scheme, and a number of his points were emphasized in the debate in the House of Commons on April 17. The right of equality, like the right of freedom, he holds, is one that can only be attributed to individuals, not to nations, the equality of nations is not only unattainable, but also neither equitable nor desirable. Like the Grotius Society and M. Lauterpecht in "The Law of Nations, the Law of Nature and the Rights of Man", Prof. Carr comes down firmly on the side of the individual. "The driving force behind any future international order," he writes, "must be a belief, however expressed, in the value of individual human beings irrespective of national affinities or allegiance and in a common and mutual obligation to promote their well-being."

Prof. Carr does not, however, visualize a supreme world directorate as an immediate objective, the sense of unity of mankind is not yet strong enough to sustain such an authority. While a world organization may be a necessary convenience and a valuable symbol, the intermediate unit is more likely to be the operative factor in the transition from nationalism to internationalism. The same caution is applied to schemes of world-wide economic organization. Nations have ceased to be convenient or even tolerable units for this purpose, and the world is not yet ready for a single comprehensive world unit. Meanwhile, the socially and internationally descriptive tendencies inherent in a multitude of planned national economies must be countered by multi-national and international planning.

As to the size and nature of such intermediate units, Prof. Carr points out that they should be appropriate for the particular end in view, and accordingly he welcomes the functional principle and the development or extension wherever appropriate of the numerous agencies of this type set up to serve the war purposes of the United Nations. Moreover, he holds that bodies like the United Nations Relief and Rehabilitation Administration and the Food and Agriculture Organization, which have been conceived on a universal basis, will be effective only in so far as they create separate organs for specific purposes in different areas. Part of the value of such functional bodies lies in the fact that, operating on national territories with the tacit or explicit consent but not formally derived authority of the national governments concerned, operating without regard to divisions or distinctions between different countries, and without affecting the sovereign powers of the national governments, they foster that multiplicity of authorities and loyalties which is essential to the health both of an international and of a national community.

This view of a developing organism rather than of a created mechanism is reflected in American opinion quoted by Prof. Carr, and seemed to be the dominant attitude to the Dumbarton Oaks proposals as expressed in the recent debate in both Houses of

Parliament. It was very clear that the scheme for Security Council was accepted only as the best that could be obtained at the moment. At the same time as Sir George Schuster pointed out, we need not assume that there will always be disagreement between the Great Powers, though it would indeed be foolish to assume that Great Britain, the United States and the U.S.S.R. will always see eye to eye on international questions of every description. It should be remembered that the peace settlement will be made, not by the new organization proposed at Dumbarton Oaks, but by the victorious belligerents and that, as Sir Arthur Salter pointed out, for about five years at least, the main interest in the international political sphere will be in the peace settlement organization of the United Nations, and also all in Britain, the United States and the U.S.S.R. In those years they can, as Mr. Churchill has expressed the hope and conviction, work together for the establishment of world peace and order and demonstrate that they can use their power to serve all nations. An entirely different attitude may prevail towards the present proposals when the Security Council really becomes effective.

Sir Arthur Salter was urging that too much should not be expected of the new organization at the start and that the limits of its responsibilities should be clearly and widely understood, so as to avoid disillusionment and loss of prestige when the new organization begins to function. For the same reason, the voting procedure may well be accepted as a temporary measure, provided it is open to revision and modification in the light of experience.

Although there was clear realization that the deliberations at San Francisco are unlikely to lead directly to a new world State, to a world police force or to federal Europe, the importance of the Conference and of agreement was fully appreciated also. Prof. Carr's prediction that the world would have to accommodate itself to the emergence of a few great multinational units in which power will be mainly concentrated—units, which culturally may best be called civilizations—was indeed tacitly assumed as correct though the solution he suggests to the dilemma of national self-determination, namely, an attempt to divorce international security and the power to maintain it from frontiers and the national sovereignty which they represent, was not mentioned. Very clearly, however, it was hoped that the habit of co-operation and common action by the Great Powers would tend to remove a predisposing cause of conflict between them, but the whole sense of the debate was with Prof. Carr in his affirmation that no international organization of power will endure unless it rests on certain common principles and pursues certain common purposes, worthy of commanding assent and loyalty of men and women throughout the world. The unifying power of the ideal of social justice in the contemporary world was well brought out by Sir George Schuster, who sensed the opportunity for leadership now awaiting Great Britain. The importance of a vigorous domestic policy in promoting understanding and *rapprochement* with the Soviet Union was also emphasized.

The conception of a balanced structure of international or multi-national groupings both for the maintenance of security and for the planned development of the economies of geographical areas and groups of nations, which Prof. Carr sees as the best prospect of international advance, has thus a good deal of general support, and readers of his book would be able to follow the San Francisco proceedings the more intelligently for its discerning treatment of some of the fundamental issues. But, like Prof Carr's impatience of nationalism makes him dismiss its claims a little too lightly, nationalism has a doughty champion in the House of Commons Sir William Beveridge. Sir William rated public opinion as of no practical importance for the prevention of aggression, but after agreeing on the difference in strength between nations and the necessity of winning the confidence of all nations in world organization, defended the idea of sovereignty and of collective security.

In doing so, Sir William essentially elaborated the argument of his book, "The Price of Peace", emphasizing the importance of establishing the rule of law for all nations. The gist of his thesis is that the abolition of war depends on finding a positive alternative to war as a means of settling disputes between nations. The only alternative which can be world-wide is compulsory arbitration by an impartial tribunal, applied to all disputes and backed by overwhelming force.

In Sir William's speech in the House of Commons he has revealed more clearly than his book the difficulties into which his legalistic rather than realist approach leads.

That alone can account for his sponsoring the legalism which, at the outset of his book, he fully rejects in so far as it is expressed in sovereignty. Indeed, his real starting point is that from which Lionel Curtis starts in his "World War—its Cause and Cure"—to which, incidentally, Sir William

tributes a foreword—Lord Lothian's Bursell Memorial Lecture and his subsequent speech to the House of Delegates and Senate of Virginia on February 17, 1940, as British Ambassador. "To-day anarchy of sovereign States cannot escape chronic or preserve individual liberty or create the conditions of prosperity or employment within their boundaries unless, in some way, they can bring themselves collectively under the reign of a single constitutional law."

With that text, Mr. Curtis has put together the substance of his earlier pamphlets. "Action", "Discipline", "Faith and Works" and "The Way to Peace", but it cannot be said that the work has been skilfully done. There is some repetition, and the argument has scarcely been improved in the process or by his diversions into history and other subjects. Mr. Curtis's sincerity and conviction cannot be mistaken, but they, like his argument, stand out in the pamphlet form in which they were first put to us. That is unfortunate, for Mr. Curtis's attitude regarding imperial defence, on which his pro-

he Price of Peace. By Sir William Beveridge. Pp 104. London: Pilot Press, 1945. 6s. net.
World War—its Cause and Cure. By Lionel Curtis. Pp xx+274. Oxford: Oxford University Press, 1945. 7s. 6d. net.

posed federal scheme is based, remains unanswered, and there is no indication as yet that that issue was really faced at the recent British Commonwealth Relations conference. If it must be recognized that there are limitations to what can be achieved at San Francisco, the very arguments regarding flexibility and an experimental and provisional approach, which were heard in Parliament, are the more reason why the British Commonwealth should make a further attempt to deal with its own problem and give the world a demonstration of the way in which a solution may be found to the larger problem.

Sir William Beveridge's legalistic approach was severely handled by Mr. Richard Law in concluding the debate in the House of Commons, but Sir William's view that the world order of to-morrow must be built on compulsory arbitration of all disputes does not constitute the sole feature of his book. Apart from the merits or demerits of his own suggestion, for which he himself disclaims any idea of novelty, pointing out that it was the basis of the Geneva Protocol, the first part of his book is a well-documented account of the experience of the last thirty years, which in itself should help many to form an independent and objective opinion on the Dumbarton Oaks scheme. It is when he passes on to discuss the conditions and methods of peace, and the scope and nature of a supernational authority, that Sir William becomes too formal and tends to overlook the necessity for a process of adjustment, compromise and agreement between those in whose hands power at present resides.

Mr. Law rightly pointed out that such processes and the establishment of confidence go to the building up of a real system of international law as well as of one of security, and he was able to some extent to reassure the House as to the qualifications which were attached to the right of veto of the Great Powers in the Yalta agreement. Mr. Law concealed no difficulties, but like Sir George Schuster he looked rather to the opportunities opening before us at San Francisco and at the inescapable fact that the only alternative to agreement and success is international anarchy, with all the implications which the closing stages of the War gave to that situation. As Lord Cranborne put it: "To-day we have another chance—it may be the last—to lift humanity out of the pit into which it has fallen. We must not, we dare not fail."

On the success of that effort depend not merely the material welfare of mankind but also the continued advance of science and every other cultural and creative activity. Moreover, though few will entertain false hopes as to the outcome of the deliberations at San Francisco or as to the immediate possibilities of whatever international organization may be set up as an outcome of that Conference, we may well reflect that we may be witnessing the approach to a science of international relationships. It is not merely that we may use organizations set up during the War for peace-time purposes, and thus promote the good will and understanding upon which international co-operation in any field, technical or political,

depends. Sir Arthur Salter has strongly urged the value of the wise use, for example, of the United Nations Relief and Rehabilitation Administration under the direction of a Supreme Reconstruction Council, and others besides him pointed out how relief work could stimulate the integration of the cultural and spiritual as well as the material side of European life. Viscount Hinchinbrooke saw in the problem which Germany itself presents a unique opportunity for an experiment in international government, and there is much in the general attitude to the San Francisco Conference which justifies the belief that something of the method and spirit of science is penetrating into international affairs.

Much clear thinking will yet be required as to the nature and meaning of nationalism, and further study must be made of its problems and the ways and means of mitigating its dangers. But while more than public opinion is clearly required to prevent aggression, Sir William Beveridge is wrong to dismiss it as of no importance. Any world authority must rest upon the support of an informed public opinion, aware of the limitations as well as the possibilities of world organizations, and understanding the restraints which must be accepted as the alternative to anarchy. Part of the task of building a science of peace must be the creation by education of such a world opinion clearly understanding the price of peace. Out of such efforts, reinforced by the scientific investigation of human relationships, designed to encourage the development in due course of an intelligence system comparable with that of the human body, there may be slowly evolved a real science of international relations. Only then can we expect to shape more precisely the large regional and international organizations adapted to serve the needs of men of all nations. Until that time comes, it behoves all men of good will to attempt to appreciate the nature of the problem of international co-operation and its bearing on their own interest and activities both as citizens and professionally, and understanding, to lend their moral support to the efforts of those who at San Francisco or elsewhere are seeking to pave the way to a better and enduring world order.

OCEANOGRAPHIC INVESTIGATIONS

The Oceans

Their Physics, Chemistry and General Biology By Profs H U Sverdrup, Martin W Johnson, and Richard H Fleming. Pp x+1,087 (New York: Prentice and Hall, Inc., London: George Allen and Unwin, Ltd., 1944) 63s net.

SVERDRUP, Johnson and Fleming have answered the demand for an up-to-date manual of oceanography with a comprehensive work, "The Oceans: Their Physics, Chemistry and General Biology". It is a large book with 1,087 pages, amply illustrated by text-figures and charts. It was published two years ago in the United States, but circulation to Great Britain was restricted until the end of last year.

Progress in oceanographical research has been exceptionally rapid during the past twenty years and the reader is warned in the preface that such recent information must sometimes be coloured in presentation by the authors' own views. At the risk of premature generalizations, they have preferred definite statements to the enumeration of uncorrelated observations, though without failing to make proper reference to alternative explanations. The success of the book is unmistakable: it will be invaluable both to specialist and beginner. In its treatment of difficult problems it does not take too much granted, though tiresome over-simplification is avoided.

The authors insist on the close inter-relation of the different aspects of oceanography, and at the Scripps Institution, where the book was written, each aspect is represented by at least one good authority. It is fortunate for the future of oceanographical research that there was such a team, working in sufficient close co-operation to cover the whole field and achieve successful joint authorship. The Scripps Institution is on the Pacific coast near La Jolla, sixteen miles north of San Diego; it is a department of the University of California. It was founded and equipped by the Scripps family, who have been great benefactors in La Jolla, and derives its funds half from the State of California, and half from the Scripps Family Research. In all branches of oceanography is encouraged, each section has great freedom, and its own grant for equipment and library. The excellent situation, facilities and atmosphere make it an ideal place for research. Prof Sverdrup has been director since 1936, and Johnson and Fleming are assistant professors.

The rapid progress made during the past twenty years is attributed partly to improved technique and partly to the application of theoretical study and laboratory research, though the frequent insistence in the book on the need for additional observations shows that theoretical treatment is now of value ahead of the work at sea. There are problems which need intensive work by several vessels, and there is still scope for extensive exploration. Where measurements have been made synoptically, over a wide network of observation points, the irregularities of physical properties and water movements have proved much greater than was expected, and this shows that great caution must be exercised in drawing conclusions from scattered observations.

The biological chapters make a detailed survey of the factors which control distribution and fertility. It is maintained that animal and plant distributions are not haphazard, but result from orderly evolutionary processes, some historical and some in continual operation. Apparent lack of order is attributed to lack of information. It is emphasized that the distribution and fertility of any species cannot be studied satisfactorily without investigating the whole life-history from egg to spawning adult; each stage may have its own particular requirements.

One of the themes of the biological section is the excellent adaptation of the animals and plants to their environment, and the advantages of sea water as a medium for supporting life. Everything needed for the maintenance of life is carried in solution—necessary gases as well as the mineral substances—except in estuaries, the stability of the physical characteristics makes highly specialized integumentary or regulatory systems unnecessary. With few exceptions the marine animals from groups with firm

ter representatives are larger than their freshwater relatives, and usually the difference is enormous. An proved food supply and more favourable rate of metabolism must be mainly responsible. Respiration probably easier in sea water owing to the presence carbonates which facilitate the removal of carbon oxide, and since the osmotic pressure of sea water nearly the same as that of the body fluids, no special energy is needed to maintain the proper equilibrium. The gradients of temperature, salinity and light intensity in the sea afford, to those animals that are able to move up and down, the opportunity selecting optimum conditions. The authors summarize the latest information on all these aspects. The single-celled plants are shown to be adapted pelagic life by their microscopic size, and the consequent high ratio of surface area to volume and sinking-rate. Where necessary they have special structures and shapes, or oil particles, to retard sinking. The most specialized forms are found in the warmer waters, and are associated with the lower viscosity of the warmer waters. It is the microscopic plants which make possible the population of large stretches of ocean, the larger plants, attached in shallow soundings, or specially adapted to a floating stence, are relatively unimportant. The authors suggest that the increased phytoplankton growth frequently observed where waters of different characteristics meet may often be due to the inoculation a sparse population, living under poor conditions, of favourable water which has lacked the spores necessary to take advantage of the good physico-chemical conditions.

With reference to the statement on page 160 that average conditions in a body of water comparable in size to the Mediterranean Sea do not change from year to year, it is felt that it would be difficult to constrate the absence of random and periodic fluctuations in the average temperature, salinity, oxygen content and contents of minor constituents, in existing data. Nor does it seem very probable that averages over longer periods, say ten years, could fail to reveal some significant changes in the range number of different species of organisms— apart from those due to overfishing. The decrease in phosphate concentration in the English Channel after 1880 and the decline of the herring fishery might be held as counter-evidence, and also the fluctuations in the northern fisheries, which are not entirely attributable to overfishing. These are, however, the fluctuations of a marginal region and rather a special case. There is another relevant statement on page 98, "for the earth as a whole, the total amount of heat that is received during one year from the sun and the limit of the atmosphere must exactly balance the total amount that in the same period is lost by radiation and radiation into space. Otherwise the temperature of the atmosphere and the oceans would change." It is not likely that the authors mean to exclude the possibility of small but significant fluctuations in the oceans.

The book gives a very practical account of the methods which have to be used in the absence of direct measurements to compute or estimate the speed and direction of ocean currents. It is worth noting that there is still no better means of judging accuracy obtainable from the practical application of Jerknes's theorem to the sea than the close agreement between Wust's calculations (1924) and Pillsbury's measurements (1889) for the Florida Current, or the measure of agreement between the move-

ments of Atlantic icebergs and the calculations of the Ice-Patrol. The same section gives the first publicity, outside enemy countries, to a new method of finding a suitable reference surface for the application of the theorem, first described by Defant in a German Atlantic Expedition report in 1941. It assumes that the surface of no motion lies in the depth interval within which the spacing of the isobaric surfaces remains more or less the same between adjoining stations. A certain amount of trial and error is necessary to find a continuous surface over a network of stations, but the method as used by Defant for the Atlantic Ocean gave results in good agreement with the best independent evidence. It has since been used in the Black Sea¹, and it will be tried extensively for other regions after the War.

From the section on tides and internal waves, it is clear that there can be large horizontal water-velocities at great depths. A mechanism exists which tends to sweep all fine material from peaks and ridges, to be deposited at greater depths. The absolute depth of the peak appears to be of no consequence, the sweeping is likely to be effective when the peak rises 500 metres above its surroundings, whether from 1,000 or 5,000 metres.

The longest chapter (157 pages) gives an excellent summary of the water masses and currents in all parts of the world. Arguing that it is rational to deal first with the simpler conditions, and gradually to enter upon the more complicated, the authors begin their survey with an account of the water circulation of the Southern Ocean, which is shown to be a very good field for oceanographical research.

Other long sections deal with the chemistry of sea water, waves and tides, marine sedimentation, organic production in the sea, the methods of making observations and collecting and the role of bacteria in the sea. The heat budgets of the oceans, differences in the balance between incoming and outgoing radiation and between evaporation and precipitation are closely considered, and throughout the book emphasis is given to the inter-relations between the oceans and the atmosphere. It is difficult to convey a true impression of the great wealth of information contained in the book. It is never likely to fail as a reference book, and it will be the starting point of many inquiries, foreseeing this, the authors have, when possible, referred to books containing comprehensive bibliographies rather than to original papers.

There are a few printer's errors, though none likely to cause serious misapprehension. It may be worth mentioning that the tonnage of the R R S *Discovery II*, quoted in Table 57, should be 1,200 tons displacement, not 2,100, and the constant at the foot of page 1,051 should be 0.02736, not 0.02763. It should also be noted that it is now common usage in English to refer to the periodical water movements accompanying the tides as tidal *streams*, keeping *currents* for the non-periodical movements due to other causes such as prevailing winds and density differences.

Of the thousand references at the ends of the chapters, half refer to American publications, a sixth to British and a sixth to German. The figures are an approximate measure of the relative efforts made in the three countries. They do not, however, reflect the importance which has been attached to oceanographical research in the Soviet Union and in Japan, probably because of the language difficulties. The Soviet Government is producing its own manual, which is likely to be the only rival to the American book for very many years. It will be a much larger

work when completed, and a glance at the first volume, although I have been unable to read it, suggests that it is more encyclopædic—mentioning almost everything that has been done

"The Oceans" will appeal to many seafarers, many ships would be glad to have a copy. There is no doubt that it will be very effective in promoting research, and increasing our knowledge of the oceans

BIRDS OF THE SOUTH-WEST PACIFIC

Birds of the South-West Pacific

A Field Guide to the Birds of the Area between Samoa, New Caledonia and Micronesia. By Ernst Mayr. Pp. xx+316+3 plates (New York: The Macmillan Company, 1945). 3/75 dollars.

AFTER the American Forces commenced operations among the Pacific Islands, the American Museum of Natural History was inundated with requests for a book on the birds of the region. There was, however, no work on the whole area published, although many papers had been written on the birds of the different groups of islands. Fortunately, a member of the staff had already made a special study of the species found in the Pacific and neighbouring areas. This was Dr. Ernst Mayr, and no one was more competent to write the present volume, since, in addition to his systematic studies, he has spent several years in New Guinea, the Bismarck Archipelago and the Solomon Islands, and accordingly was familiar with many species in the field. The area covered by this volume comprises the groups of islands from Tonga in the south to the Mariana Islands in the north, and west as far as the Solomons.

In the introduction the author gives lucid hints on how to identify birds; he points out that though there may still be a few undetermined species in the mountains of the Solomons or in New Ireland, there remains much to learn of the life-histories and habits of nearly every bird.

The volume is divided into two parts: a general survey of the species, and more detailed lists of those found in the different groups of islands. In the first part, the birds are divided into groups, the sea-birds, shore-birds, and land- and freshwater-birds. Of the sea-birds, the terns are by far the most numerous and embrace thirteen different species, but only one gull, the Australian silver-billed gull, occurs in the area. On the other hand, the petrels, ranging in size from the wandering albatross to a Mother Carey's chicken, though much fewer in numbers, are represented by more than twice as many species. The other sea-birds are the frigate and tropic birds and the widely spread boobies. With the exception of the Australian stilt, all the shore-birds are migrants from the north. Several, including the common sandpiper, turnstone and sanderling, are familiar summer and winter visitors to the British Isles. The remaining section embraces a great diversity of types: cassowaries, grebes, ducks, hornbills, sun-birds, honey-eaters and others, as well as several introduced species, namely, the Indian myna, Malay turtle dove and red-browed waxbill.

The second part gives additional details of the land- and freshwater-birds inhabiting the different groups of islands, and here the observer will discover how little is known of the habits of many species. In some of the archipelagos certain birds, such as flycatchers, whistlers (*Pachycephala*), white-eyes and honey-eaters, tend to vary and divide up into races on the different islands. Dr. Mayr does not go into details on this point, but gives just sufficient particulars to recognize the races. This area is the headquarters of the brilliantly coloured fruit pigeons which combine such a wonderful variety of tints, and New Caledonia is the home of the flightless kagu which is now in danger of extermination since it falls an easy prey to prowling native dogs. The gems of the parrot-world, the tiny pygmy parrots, no more than 3½ in. long, are found in the Solomons, where they bore holes in the nests of tree-haunting terns where they deposit their eggs. They are reported to feed on their hosts or possibly fungi.

There is a map on the inside of the cover, the coloured plates and sixteen line drawings which will facilitate the naming of species.

Dr. Mayr is to be congratulated on the production of this small work at such short notice, and there is no doubt it will be welcomed by the troops in the Pacific.

ELEMENTARY ZOOLOGY

A Manual of Elementary Zoology

By Dr. L. A. Borradaile (Oxford Medical Publications). Eleventh edition. Pp. xiii+813 (London: New York and Toronto: Oxford University Press, 1945). 24s. net.

THE first edition of "Borradaile" appeared in 1912 and the second only in 1918. The start was no doubt due to the first World War, and it is interesting to compare the book's record in the second. At some time in 1939 there was a second impression of the ninth edition, then came the tenth edition in 1941, its second impression in 1943, and now the eleventh edition in 1945. One wonders how many students this very valuable book has helped through the bewilderment of their first contact with zoological facts and ideas, and how many professional zoologists it has extricated from class-room and other difficulties. The publishers do not announce the sales, but they must now be very many thousands.

The new edition continues the book's development. There is increased attention to problems of function, reducing the force of the criticism made by some that the book devotes to these subjects less attention than is due even in an elementary text. In addition there are some important changes in the chapters on embryology, where the development of *Amphioxus* is now based on Conklin's description. The account of gastrulation in the chick is the classical story of delamination, but more recent views are mentioned. The sections on genetics are somewhat expanded with some discussion of mutation and recombination and there are new diagrams of meiosis and crossing over. A new passage which should stir the interest of any intelligent student is that on the "History of the Vertebrata" in Chapter 22. Altogether, there are some fifty new figures.

The value of the book is proved by the number of its editions and reprintings; it is to be hoped that many more lie in the future.

P. D. F. MURRAY

SEAWEED RAYON

By PROF. J. B. SPEAKMAN

Textile Chemistry Laboratory, University of Leeds

DRY seaweed contains 15–40 per cent of alginic acid¹, which is readily extracted with sodium carbonate solution². Sodium alginate was available in powder form before the War, but no serious attempt had been made to examine its possibilities as a raw material for the manufacture of rayon, despite the existence of abundant supplies of seaweed off the west coasts of Scotland and Ireland, and the ease with which filaments are obtained when a solution of sodium alginate is extruded into baths containing inorganic acid or a salt of a suitable polyvalent metal. Unfortunately, these favourable characteristics were overshadowed in the minds of early observers by the fact that the salts of alginic acid—or such of them as were examined—were found to be soluble in solutions of soap and soda. There seemed to be little purpose in devising satisfactory methods of spinning alginate rayons when the fabrics made therefrom would dissolve in the solutions commonly used in laundering textile materials. Furthermore, the prospect of producing alkali-resistant alginate rayons must have seemed remote in the absence of exact information about the constitution of alginic acid.

Alginic acid was recognized as a polymer of *D*-mannuronic acid in 1930³, but the precise mode of polymerization has since been the subject of much discussion. In the light of recent determinations of the equivalent weight⁴, the simple preparation of the di-acetyl derivative⁵, and an X-ray examination of well-oriented alginic acid filaments⁶, there can now be little doubt about the correctness of the constitution proposed by Lunde, Heen and Øy¹, supported by Hirst, Jones and Jones⁷ [see also p. 667], namely:

The molecular weight of the polymer is high, but varies with the mode of isolation: osmotic pressure determinations on a series of sodium alginates, dissolved in 0.2 *N* sodium chloride solution, gave values ranging from 48,000 to 185,000⁸. All such alginates should clearly be capable of successful use in the production of rayon, especially as the viscosity of relatively dilute solutions is great enough to permit successful spinning on the viscose system. In the early years of the War, therefore, when it seemed essential to make the fullest possible use in Britain of home-produced raw materials, the possibility of making rayon from seaweed was investigated.

Although the main purpose of the work was the production of alkali-resistant alginate rayon, the general problems involved in spinning satisfactory yarn from sodium alginate—satisfactory in appearance, feel and strength—were first investigated⁴ in two simple cases, namely, the spinning of calcium alginate and alginic acid yarns, both of which are soluble in sodium carbonate solution. The equipment used was similar to that employed in spinning viscose

rayon. A 5 per cent solution of sodium alginate was forced through a candle filter to a gear-wheel pump, which delivered the solution to a tantalum spinnerette immersed in a bath of acidified calcium chloride. In the preliminary experiments the spinnerette had twenty-one 0.1 mm. holes, and the resulting 21-filament yarn was drawn off by a glass revolving godet from which it passed through a traversing funnel into a Topham box revolving at 3,000 r.p.m. Here the yarn was collected in cake form. It was then washed, reeled into hanks and dried.

As produced in this way, the yarn was useless as a textile material: its handle was harsh and straw-like because the component filaments, which are highly swollen when first spun, adhere to one another during drying. The difficulty was overcome by extruding sodium alginate solution into a coagulating bath containing emulsified oil⁹, the filaments being thus coated with a film of oil which prevents adhesion. Although greatly improved, the handle and appearance of the resulting yarn were still unsatisfactory, owing to the irregular ribbon-like form of each filament. It was then found that the cross-section of the filaments became more and more nearly circular as the concentration of sodium alginate in the spinning solution was increased. Yarn of excellent handle and appearance was finally obtained by extruding a 7.5–8.0 per cent (w/w) solution of sodium alginate into a coagulating bath containing calcium chloride (1.0 *N*), hydrochloric acid (0.02 *N*) and 2.5 per cent by volume of olive oil emulsified with a neutral detergent such as 'Lissapol C' (I.C.I.). The tenacity of the yarn was, however, rather low, being no more than 1.23 gm./denier* at 64.8 per cent relative humidity, compared with values of about 1.3 and 1.8 gm./denier for cellulose acetate and viscose rayons, respectively. The weakness of the calcium alginate rayon was ultimately traced to two causes: degradation by acid carried over from the coagulating bath during the time the cake is being spun, and mechanical damage to the freshly spun, swollen filaments when the yarn is reeled into hank form for drying. The first difficulty was overcome by washing the yarn as it traversed the godet on its way to the Topham box; and the second by leading the yarn from the cake through running water, then through a dryer, and winding directly on to bobbins. With these refinements, no difficulty was encountered in producing yarns with a tenacity of 1.8–2.1 gm./denier at 64.8 per cent relative humidity.

Attention was next turned to alginic acid rayon, which is more difficult to spin because, in the absence of metal-containing cross-linkages, the filaments are weak and highly swollen. To prevent filament adhesion during drying, it was found necessary to emulsify the oil in the coagulating bath with a cation-active agent, such as 'Fixanol' (I.C.I.), which is adsorbed by the filaments. Good results were obtained by extruding sodium alginate solution into a coagulating bath containing sulphuric acid (1.0 *N*) saturated with sodium sulphate and 2.5 per cent by volume of olive oil emulsified with 1 per cent (w/v) of 'Fixanol'.

It is, however, unlikely that alginic acid yarn will ever be produced on the large scale because of the rapidity with which it undergoes degradation during storage. Even when kept in the dark at 65 per cent relative humidity and 22.2° C., the tenacity of a well-washed alginic acid yarn fell from 1.06 gm./denier after 28 days to 0.36 gm./denier after 480 days¹⁰.

* The denier of a yarn is the weight in grams of 9,000 metres.

Fig. 1.

Well-washed calcium alginate yarn, on the other hand, can be stored for periods up to at least thirty weeks without significant loss of strength, and can be converted into alginic acid yarn, whenever necessary, by mere washing with cold, dilute hydrochloric acid.

As soon as satisfactory methods of spinning alginate rayons had been devised, the possibility of producing alkali-resistant rayons was investigated. It seemed likely that success might be achieved by cross-linking alginic acid with metals of high co-ordinating power, such as chromium¹¹ and beryllium¹², instead of with calcium. When, however, sodium alginate solution was extruded into baths containing chrome alum and beryllium sulphate, the resulting yarns were harsh, wiry and brittle, despite the presence of emulsified oil and cation-active agents in the coagulating baths⁴. Direct spinning of chromium and beryllium alginate rayons was found to be impossible, but when calcium alginate rayon was treated with a 2 per cent solution of one-third basic chromium acetate¹³ at 25° C., calcium was displaced by chromium. The extent of displacement increased with increasing time of treatment, but yarn containing as little as 1.29 per cent chromium, while retaining 9.04 per cent calcium, was undissolved after immersion for twenty-four hours in a solution of soap and soda at room temperature. Similarly, a yarn containing 2.89 per cent beryllium and 5.20 per cent calcium, prepared by treating calcium alginate rayon with a 2 per cent solution of basic beryllium acetate⁴ at room temperature, was found to be alkali-resistant. In both cases, the stability of the yarns appears to be due to co-ordination of the metal—chromium or beryllium—with the hydroxyl groups of alginic acid.

Still better yarns were obtained—better in being free from calcium—by treating alginic acid yarn, derived from calcium alginate yarn, with the basic acetates of the metals. Prepared in this way, both chromium and beryllium alginate rayons suffer less than 5 per cent loss in tenacity on treatment with a solution of soap and soda for thirty minutes at 25° C. or 40° C., and the beryllium alginate rayon, which is more useful in being uncoloured, has a tenacity of more than 2.0 gm./denier.

Alkali-resistant rayon can also be obtained by cross-linking alginic acid yarn with formaldehyde¹⁴ instead of co-ordinating metals. Cross-linking is

brought about by impregnating the yarn with a solution of ammonium chloride and formaldehyde at pH 3, and then drying at 95° C. As the carboxy groups of the treated filaments are free, the yarn though undissolved, is swollen by alkalis, but swelling can be restricted by further treatment with the basic acetates of chromium and beryllium.

Ultimately, therefore, the basis of all the alkali-resistant seaweed rayons is calcium alginate rayon which is cheap and easily spun, and possesses satisfactory elastic properties for weaving and knitting. For these reasons it seems likely that calcium alginate rayon will form the stock material for all purposes for conversion into woven and knitted fabrics, which can be made alkali-resistant in finishing, as well as for special uses in which advantage is taken of its solubility in alkalis. These special uses¹⁵, which are now so numerous as to make the alkali-soluble rayon as important as the alkali-resistant varieties, were developed in the belief that a defect can always be turned to advantage. Two illustrations will perhaps serve to indicate the power which has thus been placed in the hands of the textile designer. When a fabric is woven from yarn prepared by twisting together cotton and calcium alginate yarns in such a way as exactly to remove the twist from the cotton yarn, subsequent scouring leaves a cotton fabric composed of yarns entirely without twist; fabrics of this type have already found a number of important practical applications. Secondly, if a fabric is woven from yarns prepared by twisting together mohair and calcium alginate yarns in such a way as to persuade the mohair to wrap around the alginate, the extra length of mohair is released to form loops on the surface of the cloth, as shown in Fig. 1, when the fabric is scoured in a solution of soap and soda. The 'disappearing fibre' technique has, in fact, simplified the methods of manufacture of a large number of fabrics, besides indicating how a number of new effects may be obtained.

Fig. 2.

Fig. 3.

In view of the importance of calcium alginate rayon, its properties have been examined in greater detail than those of other alginates. The yarn as a relatively high tenacity, varying from 1.8 to 1 gm/denier, with an extension at break of about 10 per cent at 64.8 per cent relative humidity because of its high metal content (about 10.4 per cent), calcium alginate has the rather high density of 7.8 when dry, but the presence of the metal has the great advantage of making the material totally non-flammable, a property which is shared by other metal alginates. All the alginates have a high water-absorption capacity, higher than that of other textile fibres, as shown in Fig. 2, where the adsorption and desorption isotherms of calcium alginate and wool at 5° C are reproduced. In general, the water-adsorption capacity increases with increasing metal content, closely related results being given by alginates

Fig. 4

derived from metals in the same group of the Periodic Table. This interesting observation is illustrated by the curves of Fig. 3, where the amounts of water adsorbed by a series of calcium and barium alginates at 64.8 per cent relative humidity and 22.2° C are shown as a function of the metal content. As would be expected, too, the breaking load of calcium alginate yarns increases with increasing metal content, on account of the increasing number of cross-linkages between the chain molecules, but since the density of the yarn also increases, there is an optimum metal content for maximum tenacity (gm/denier) as shown in Fig. 4.

Alginate rayons have a marked affinity for basic dyes. In addition, they can be dyed with selected direct dyes and, when the yarns contain chromium or beryllium, with mordant dyes. There is, therefore, good reason to believe that the seaweed rayons will find an important place in the textile industry of the future.

THE CHANGE FROM TRICHROMATIC TO DICHROMATIC VISION IN THE HUMAN RETINA

By PROF. H. HARTRIDGE, F.R.S.

MANY years ago I noticed the confusion of yellow with white, and blue with black when test objects of small size are under critical examination¹. I thought, incorrectly, that this confusion was due to the chromatic aberration of the eye. Some years previously, König had, unknown to me, given the true explanation of the phenomenon, namely, that for objects of small size, examined by the fovea centralis, trichromatic vision is replaced by dichromatic vision². He thought that this change was strictly limited to the fovea centralis. Recently Willmer has come to the same conclusion³. Both König and Willmer are mistaken, however, for in a recent communication in *Nature*, I have produced evidence that the change occurs not only at the fovea centralis but practically all over the useful retina⁴. Further evidence on this point has now been obtained, together with many other facts, concerning the appearance of the colours of very small objects.

1. *Effect of angle of view.* Before beginning this section it is necessary to point out the difference between angle of view and visual angle. By the former is meant the angle between the fixation axis and the line joining the centre of the test object with the eye. By the latter is meant the angle between

the lines joining the edges of the test object with the eye. Thus when the centre of the image of the test object falls on the fovea centralis, the angle of view is zero. When, however, the observer directs his gaze more and more to one side of the test object, the angle of view increases in value, while the visual angle stays constant.

During the tests on the effect of angle of view, a yellow test object, 6 mm square, was viewed on a black ground in daylight. Four small blue-green fixation marks were placed on the background with their centres 4, 8, 12 and 16 cm below the centre of the test object. Each observer determined (1) the distance at which the test object was definitely yellow, (2) the distance at which it appeared to be white, (3) the distance at which the transition from yellow to white occurred. The observer fixated the test object or one of the blue-green fixation marks as might be required. The results are shown in the following table.

		Fixation at				
		0	4	8	12	16 cm
H H		6.5 metres	8.5 metres	12.0 metres	23.0 metres	12.0 metres
1	11.0	"	11.5	"	19.5	"
2	11.0	"	11.5	"	27.0	"
3	9.0	"	9.5	"	24.5	"
J L d'S						
1	18.5	"	22.0	"	27.0	"
2	24.0	"	28.5	"	34.0	"
3	22.5	"	25.0	"	31.0	"
E. C T						
1	16.0	"	13.0	"	11.0	"
2	21.5	"	21.0	"	19.0	"
3	18.5	"	18.0	"	16.0	"
G N J						
1	5.5	"	8.5	"	7.5	"
2	10.5	"	12.0	"	12.0	"
3	8.0	"	10.0	"	13.0	"

The above table brings out two points: that the transition from yellow to white occurs at peripheral parts of the retina just as it does at central parts, and that considerable variations in detail occur between different observers.

I have assumed that the transition from yellow to white indicates that trichromatic vision has been replaced by dichromatic vision. Evidence on this point will be found in Section 13 of this article. On the assumption that this evidence is acceptable, the following statement can be made. For test objects of average size the colour vision of normal persons is approximately trichromatic, while for test objects of sufficiently small size, colour vision is nearly dichromatic (see Section 14). The transition occurs at a given distance from the eye for a particular size of test object which depends on several factors. Two of these are shown in this section to be the observer, and the angle of view.

2 *Importance of area of test object* The distance between object and observer at which the transition from yellow to white takes place might depend, for example, on the area of retina which is being stimulated, or on the quantity of light which is falling on the retina, or on the length of contour of the test object. Various tests were carried out on these lines, and area was found to be an important factor. In the following table the distances are recorded at which two yellow test objects of the same area but of different shape were found to become white.

	Square test object	Oblong test object
Length	12 mm.	6 mm
Width	12 "	24 "
Length of contour	48 "	60 "
E. C. T	28.5 metres	26.5 metres
J L d'S	28.0 "	25.5 "
E. B C	26.0 "	27.0 "
H H	16.0 "	18.0 "

Observer H H knew that the two areas were equal. Observers E C T, J L d'S and E B C were unaware of the nature of the experiment, and their observations were therefore free from bias. In the case of each one of them the conclusion is that neither shape nor length of contour has any obvious effect on the distance at which yellow becomes white.

This conclusion was deemed to be of sufficient importance for a further test to be justified. On test object consisted as before of a yellow square on a black ground. The other consisted of a yellow square of precisely the same dimensions as the first and from which a U-shaped piece had been cut leaving a π -shaped piece behind. These two pieces were placed near one another, but not touching, on a black ground and were together used as the test object.

First the uncut square was presented to the observer and then the cut one. The results obtained were as follows.

	Uncut square test object	Cut square test object
Area	144 sq mm	144 sq mm
Length of contour	48 mm	128 mm
E. B C	20.5 metres	19.5 metres
J L d'S	25.7 "	27.7 "
E C T	28.7 "	29.3 "

In this case also, the differences in distance are small and within the probable experimental error, so that in spite of the great difference in the shape and in the length of contour of the two test objects they change colour at the same distance from the eye.

These tests show that neither shape nor length of contour are important factors in determining the distance at which the change from yellow to white takes place.

Further evidence on this point will be found in Section 10.

That alteration in size greatly affects the distance in metres at which the transition from yellow to white takes place is shown in the following table.

	J L d'S	G W J	H. H	E C T	J E T	Mean
Size						
6 mm	6.1	8.0	9.3	10.7	13.5	9.9
12 "	11.8	10.1	17.7	17.7	18.8	15.2
24 "	19.3	20.3	30.0	25.3	23.3	23.6

All these test objects were yellow squares on black ground, one had 6-mm sides, whereas the other two had sides of 12 mm and 24 mm respectively. It would be expected that a doubling of the side of the square would double the distance at which the transition took place. This was found not to be the case for any one of the observers. The cause of the discrepancy is probably that, as the observer increased his distance from the test object, alteration took place in the images falling on peripheral parts of the retina.

3 *Effect of eye movements* König noticed the difficulty of holding the test object constantly on the fovea centralis². The slightest movement led to the re-establishment of normal trichromatic vision. This was this observation that led him to suppose that area of dichromatic vision to be very small.

I have also noticed this difficulty, but I have found that it occurs not only in the fovea centralis, but also in parts of the retina considerably peripheral to it. Thus when the image of a yellow test object falls on one side of the fovea centralis, and exact fixation is performed, the yellow is replaced by white and remains white during exact fixation. On the slightest movement performed by the observer's eye, however, the true yellow colour of the test object is momentary.

rily disclosed to view. The explanation of this phenomenon is that the change from trichromatic to dichromatic vision occurs locally, being limited to the area on which the image of the test object falls, but if the test object be moved, or the eye axis be altered, a fresh area of retina is involved and for a moment reacts in a normal trichromatic manner. Then it too changes, and becomes dichromatic.

4 *Effect of simultaneous presentation.* From past experience it was expected that simultaneous contrast would affect the apparent colour of the test object. Thus if an observer stood at a distance from a yellow test object on a black ground so that the former was at the transition point between yellow and white, then it would be expected that the close proximity of a white area would, owing to contrast, cause the test object to appear yellow, and that similarly the close proximity of a yellow area would cause the test object to appear white. Tests showed that precisely the opposite took place, for when the white area was placed in position the test object appeared white, and when the yellow area was placed in position the test object appeared yellow.

The cause of this phenomenon probably is that the test object, and the coloured area that has been placed near it, form together a single stimulus to the retina, and their combined areas are taken into account when determining whether or not the change from trichromatic vision to dichromatic vision shall occur (see Section 10). Thus a single yellow test object may be viewed at such a distance that it has the appearance of being white, but, on placing a second yellow test object close to it, it immediatelyverts to yellow. One test object alone is so small that dichromatic vision is replaced by dichromatic vision. Then, however, there are two such objects in the visual field, their combined areas may be too large for dichromatic vision to be possible, and in consequence there is a return to trichromatic vision.

5 *Spatial effect.* It has been shown in the previous section that the close proximity of a yellow area biases the test object towards yellowness, and that similarly a white area biases it towards whiteness. In this section the effect of distance between the test object and the coloured 'biasing' area will be dealt with. The test object was a yellow square with 12 mm sides. The 'biasing' area was a yellow rectangle 10 mm high and 25 mm wide. This was placed at various distances from, and to the left-hand side of, the test object. On the other side of the test object is a white 'comparison' area 100 mm high and 25 mm wide. This was placed at a constant distance of 20 cm. from, and to the right-hand side of, the test object. The results obtained were as follows:

Distance between test object and 'biasing' area	Distance for test object to appear white
Infinity	8.8 metres
20 cm	12.5 "
10 "	18.5 "
5 "	23.0 "
0.5 "	38.0 "

It will be seen that as the distance between the 'biasing' area and the test object is reduced, the greater the distance becomes at which the test object appears white.

6 *Overlap.* On numerous occasions it has been noticed that the change from trichromatic to dichromatic vision does not occur sharply, nor does it always occur when the test object is at the same distance from the observer. Sometimes the phenomenon of overlap is observed. The change from low to white may occur at a considerably greater

distance between test object and observer than the reverse change from white to yellow. Overlap is more likely to be observed when very careful fixation is being preserved, for the slightest eye movement reduces it considerably. It is as if the mechanism causing the change in vision suffered from backlash, and that small eye movements have the effect of reducing this.

7 *Effect of brightness of illumination of the test object.* Unfortunately, it has not been possible owing to war conditions to perform any precise measurements on the effect of illumination on the change from trichromatic to dichromatic vision. On a number of occasions, however, tests have been made to see if the intensity of illumination of the test object plays an important part. The reason for making these tests is that since the change-over depends on the area of the test object, and not on its shape (see Section 2), it might be that the total amount of light reaching the retina is really the determining factor; in other words, the product of area and illumination, allowance being made for any variations in the diameter of the pupil. Illuminations of 1-3,000 ft. candles approximately have been tested, using an artificial pupil of 1.5 mm. There is no doubt that light intensity plays some part as the following values show:

A yellow test object 6 mm square changed to white at following distances			
1 ft. c	12 ft. c	100 ft. c	3000 ft. c
1.7 metres	3 metres	8 metres	18 metres

Illumination does not play the important part, however, which it would do if total light reaching the retina was the criterion. For change in illumination of 1 to 3,000 ft. c. would then be accompanied by a change of distance in the ratio of 1 to 55. Change in the degree of light adaptation may well have taken place in the above experiments. The possible effect of this will now be explored.

8 *Effect of adaptation.* The effect of adaptation on the distance at which a yellow test object becomes white has been tested by taking two adaptation levels: light adaptation by gazing for 1 min. at the sky, and dark adaptation by excluding light from the eyes for 5 min. It was realized that neither full light adaptation nor full dark adaptation would be obtained in such short times. The object of this experiment was to ascertain if adaptation produced a noticeable change in the distance at which the test object changed colour.

The result obtained was far from satisfactory. On some occasions light adaptation seemed to increase the distance, whereas on others it seemed to produce no effect or even a slight decrease. On the whole, some increase of distance seems to be produced, but the effect is not a marked one. It might account in part, however, for the increase in distance with illumination noted in the previous section.

9 *Effect of depth of tint of test object.* If several yellow test objects of the same shape and size, but of different depth of tint, be tested as before, it will be found that very obvious variations occur in the distances from the observer at which they become a neutral tint: white in the case of the paler shades of yellow, but grey in the case of the darker shades. The following example is typical of the results obtained:

Colour of test object	Distance in metres
Pale lemon yellow	12.5
Daffodil yellow	18.0
Chrome yellow	27.0

As might be expected, a deep tint requires a greater distance than a pale one, since in the latter case the colour is already diluted with white light

10. *Effect of the shape of the test object* Two experiments have been described in Section 2 in support of the statement that it is area and not shape which determines the distance at which a yellow test object changes to white. It is, however, only necessary to take an extreme case to see that this cannot always be the case. Suppose, for example, that the whole or an important part of the image fell on the blind spot, then that part, at all events, would contribute little if at all to the stimulation of the retina. It is possible also that parts of the test object falling outside the fovea will have a significantly different effect from those parts which fall inside it. To test this possibility two test objects were compared. One as before consisted of a yellow square with 12 mm sides, the other consisted of a similar square which had been divided into nine squares each with 4 mm sides. One of these squares, which was used as the fixation point, was mounted on the centre of a black ground, the others were mounted in a ring of 10 cm. radius around the central one to form a star. The following distances were obtained:

	Square test object (area, 144 sq mm)	Star test object (area, 144 sq mm)
G N J	yellow at 8.5	5.5
	white at 12.2	12.0
	mean 10.4	8.8
H H	yellow at 11.6	6.6
	white at 15.0	11.5
	mean 13.3	9.0
J L. d'S.	yellow at 17.7	15.0
	white at 23.7	21.7
	mean 20.7	18.4
E C. T.	yellow at 7.0	7.5
	white at 16.0	15.0
	mean 11.5	11.3

All four observers found that a somewhat greater distance was required for the square than for the star. In the case of any one observer, the differences are probably within the experimental error; but since all four observers found the differences in the same direction, I think they are significant. It is not, however, the magnitude of these differences which I wish to emphasize, but on the contrary their smallness. They indicate the apparently extraordinary facility with which the retina integrates the various parts of a pattern so as to ascertain the total area.

Until further experiments have been performed the following provisional statement may be made. provided that no part of a pattern falls on the blind spot or on some other defective area of the retina, and provided that the parts of a pattern are not too widely separated, the retina integrates the various parts of the pattern so as to arrive at the total area.

11. *Effect of pupil diameter* Artificial pupils were used to reduce the aperture of the eye to the required size, and the effect on the distances at which a yellow test object on a black ground became white were determined.

Pupil diameter	Illumination rates	Distance at which yellow becomes white
5.7 mm.	32.5	15.0 metres
4.8 "	23.0	10.5 "
4.0 "	16.0	9.1 "
3.2 "	10.2	8.6 "
2.4 "	5.8	7.5 "
1.6 "	2.6	6.2 "
1.0 "	1.0	5.0 "

As the aperture of the eye is reduced in size, the distance from the observer to the test object becomes less. Now a reduction in aperture is accompanied by

a reduction in the light intensity reaching the retina and, as seen in Section 7, the latter is accompanied by a decrease in the distance at which yellow becomes white. In Section 7 it was found that an increase in illumination from 1 ft c to 100 ft c required an increase in distance from 1.7 to 8 metres, that is 4.7 times. This increase corresponds reasonably well with that given by the change in pupil diameter Δ , suggested in Section 8, the effect of change in illumination may be due to a change in retinal adaptation. It is possible that the effect of change of pupil diameter here recorded may have a similar cause.

12. *Effect of colour of the background* It seems likely that a yellow test object on a blue ground would tend to retain its colour more readily than on a black ground, because the blue ground would enhance the yellow colour by simultaneous contrast. Experiments showed that the exact opposite is the case, as the following results show.

Colour of background	Distance at which yellow becomes white
Black	17.4 metres
Blue	9.3 "

The explanation given previously appears to be correct, namely, that the chromatic aberration of the eye causes the blue ground to overlay the yellow test object and therefore to reduce its yellowness since blue and yellow are complementary in colour to one another⁷. The following observations support this conclusion. The effect of pupil diameter on the distance at which a yellow test object on a blue ground becomes white is shown in the table below.

Pupil diameter	Distance at which yellow becomes white	
	on blue ground	on black ground
5.7 mm	8.3 metres	15.0 metres
4.8 "	8.5 "	10.5 "
4.0 "	8.6 "	9.1 "
3.2 "	8.0 "	8.6 "
2.8 "	7.3 "	—
2.4 "	6.0 "	7.5 "
2.0 "	6.5 "	—
1.6 "	5.6 "	6.2 "
1.3 "	5.2 "	—
1.0 "	5.0 "	5.0 "

If the values in the second column be compared with those given in the previous section, which are repeated in the third column above, it will be seen that with large pupils the substitution of the blue ground for the black one greatly reduces the distance at which yellow becomes white, but that as the pupil is reduced in size, the difference gets less and less until at 1 mm aperture the difference disappears entirely. The explanation is as follows. With large pupils the effect of chromatic aberration is considerable, and since blue rays come to a different focus from yellow rays, the latter are mixed with blue former to produce white, when a yellow test object lies on a blue ground. This is not the case, however, when a yellow test object lies on a black one. Consequently, the latter requires a greater distance for yellow to become white than does the former. With small pupils, on the contrary, the effect of chromatic aberration is small, so that scarcely any mixing of test object with background takes place. In consequence, the substitution of a blue ground for black one has scarcely any effect on the distance at which the yellow test object becomes white.

13. *Effect of the colour of the test object* In previous sections the experiments described have been limited to yellow test objects, because it was considered better to concentrate on one colour rather

han⁶ to describe the use of one colour for one test and another colour for a different test. The main conclusions reached with yellow have, however, been tested with other colours, namely, green, blue, purple and crimson. Green on a black ground both at the fovea and the periphery becomes blue-green, and so does blue. Purple becomes reddish-brown, and crimson becomes orange. In no case has an observation been made which would lead to the conclusion that the change, either at the fovea centralis or at the more peripheral parts of the retina, is not one of dichromatism of the type described previously. Therefore, so far as is known at present, all the experiments described using a yellow test object could be done equally well, and with a similar result, with a test object of any of the other colours mentioned above.

14 *Nature of the dichromatism* When studying the changes in colour which take place when very small test objects are looked at, three unexpected observations were made.

(1) The short-wave end of the spectrum was expected to be blue-green, precisely complementary to red. It seemed, however, to be too blue for this to be the case.

(2) Instead of orange appearing to be red diluted with white, as would be the case if true dichromatic vision was present in the retina, it was found that orange retained its natural colour.

(3) It was observed that crimson, which was expected to become some shade of red mixed with white, actually became orange.

All the above anomalies obviously require explaining. In the first place, an explanation was sought on Young's theory of trichromatic vision without a satisfactory result, so that an alternative explanation was sought for. This was obtained on the basis of Granit's results with mammalian retinas using micro electrodes⁵.

Granit, in a private communication, has informed me that he has obtained evidence of seven varieties of modulator in the mammalian retina: two red ones at 600 λ (common) and at 580 λ (less common), two green ones at 540 λ , at 520 λ , and at 500 λ , and two blue ones at 460 λ and at 330 λ .

Now if the dichromatism left unchanged the two red receptors at 600 λ and 580 λ , but converted all the remainder except the blue ones into a single sensation, then a modified form of trichromatic vision could result, namely: red due to the sense organ for 600 λ , orange due to the sense organ for 580 λ , and greenish-blue due to the connecting together of the sense organs for 540 λ , 520 λ and 500 λ with the green and blue visual centres (see Section 15).

Such vision would, I think, account for (a) the reception of orange as being different from red mixed with white, (b) the modification of crimson to orange, and lastly (c) the fact that the blue-green sensation has a strong predominance of blue.

15 *Hypotheses of the change from tri- to dichromatic vision*

Hypothesis 1. The change resembles simultaneous contrast in affecting the margins of the test object. Thus, suppose a yellow test object on a black ground appear to the eye to have a narrow white margin, then as the test object is reduced in size the white margin should encroach more and more on the yellow central area until the whole of the test object has become white. This hypothesis was tested in two ways. (a) By taking two yellow test objects of the same area but very different shape, one square and

one oblong. If this hypothesis were true, the square test object would require a much greater distance than the oblong one in order to become white. Experiments showed, however, that the two distances were nearly the same (see Section 2). (b) By taking two oblong test objects of the same shape and size, one having yellow edges and white centre, the other having white edges and a yellow centre, both on black backgrounds, the yellow areas being equal. If this hypothesis were true, the former ought to appear white at a shorter distance than the latter. Experiment showed the two distances to be nearly the same. This hypothesis must therefore be abandoned.

Hypothesis 2. That it is due to stray light entering the eye from surrounding objects. This hypothesis was tested by causing the observer to look down a narrow blackened tube at the yellow test object, the distance at which the transition of yellow to white occurred being noted. This distance was found to be the same as that obtained without the tube, so that stray light does not appear to be a contributory cause.

Other hypotheses similarly tested were (3) that it is due to the chromatic aberration of the eye, (4) that it is due to haze between the test object and the observer. As none of these hypotheses explained the phenomenon, a physiological explanation must be looked for, such as the cancellation of a sensation as in protanopia (red blindness), or the linking of two sensations as in deutanopia (green blindness)⁸.

16 *Cancellation and linking* Cancellation of the red sensation would cause white to appear blue-green, cancellation of the green sensation would similarly cause white to appear purple, while cancellation of the blue sensation would cause white to appear yellow⁴. Since white does not change in any of these ways, cancellation does not appear to account for the phenomena which are observed. Linking of red and green would cause one end of the spectrum to appear yellow and the other end blue. Linking of red and blue would cause both ends of the spectrum to appear purple, and the middle region to appear green. Linking of green and blue would cause one end of the spectrum to appear red and the other end blue-green. Of the three types of linking it is obvious that the last most closely fits the observed facts.

In one important respect, however, this plan requires modification, namely, with regard to the blue and violet parts of the spectrum. If there were simple linking and nothing more, then the blue and violet parts of the spectrum would be modified in colour to blue-green, but would retain their normal brightness when seen at small visual angles. Such, however, is not found to be the case, for there is always a considerable reduction of brightness in the case of both colours. When a very bright spectrum, such as that of a carbon arc, is examined in such a way that it subtends a very small angle at the eye, its short-wave end is found to terminate at the same wave-length as it does when it subtends a large angle at the eye. When, however, a spectrum of average brightness is examined in the same manner, then there is seen to be considerable shortening of the short-wave end when it subtends a small angle at the eye, but little or no shortening when it subtends a large angle. This fits in with the observation that blue and violet test objects lit by ordinary daylight appear dark grey or black when they subtend small angles at the eye. If now their intensities be greatly increased, then both are seen to be blue-green in colour. A hypothesis which fits all the above facts is

that for test objects subtending small visual angles the brain centres for green and blue are linked together and are connected with the sense organs responding to green rays, while at the same time the sense organs responding to blue rays are temporarily put out of action.

17 *Nervous level of the mechanism*. A question which naturally presents itself concerns the position of this linking and cancelling mechanism. Is it situated in the retina, or in some part of the brain?

The following experiment points to a definite location. A grey test object is placed on a bright blue background in order to produce a yellow coloration of the former by simultaneous contrast. If now the distance between test object and observer be increased, it is found that the yellow coloration diminishes and at a certain distance disappears altogether, being replaced by white. This experiment shows that a subjective yellow behaves in the same way as a real yellow does with decrease in visual angle, and the mechanism producing the change must therefore operate on both. This mechanism must therefore be situated at a higher nervous level than the one which is responsible for simultaneous contrast. Now in Burch's celebrated experiment⁶ in which, using a stereoscope, a grey test object on a blue ground was presented to one eye while another grey test object on a red ground was presented to the other, the two coloured grounds fused to form a single purple ground, but the grey test objects retained their individuality, that on the blue ground remaining yellow, that on the red ground remaining blue-green. This experiment showed that simultaneous contrast occurs at a nervous level below that at which binocular fusion occurs.

Now as we have said above, the mechanism for converting trichromatic to dichromatic vision appears to be situated at a higher nervous level than that responsible for simultaneous contrast. It might therefore be either between the levels for simultaneous contrast and binocular fusion or above both levels. Evidence has been obtained and will be described elsewhere that the former is probably the case.

I would like to express my thanks to those who have acted as observers for me.

OBITUARIES

Sir Ambrose Fleming, F.R.S.

JOHN AMBROSE FLEMING was born at Lancaster on November 29, 1849, and died at Sidmouth on April 18. He was the eldest son of the Rev James Fleming. His mother was a daughter of John Bazley White, an engineer who pioneered the manufacture of Portland cement in Kent. About 1856 the Fleming family moved to London and in 1863 Fleming entered University College School. He has recorded that he was always at the bottom of the Latin classes though quick at mechanics and science. Evidently in these respects he was nearer his maternal grandfather than his father.

In 1866 Fleming entered University College, but he had to leave before graduating. For a year he worked in a shipwright's drawing office and then for two years as a stockbroker's clerk. In his leisure he prepared for the B.Sc. degree. In 1871 he became science master at Rossall School, and in two years saved enough to allow him to enter the Royal College of Chemistry, South Kensington. There, under Franklin, he began his research career, and in 1874 read his first paper, on a form of voltaic cell, at the first meeting of the Physical Society of London. His funds being spent, he went as science master to Cheltenham College and in two years saved enough to enter St John's College, Cambridge, at the age of twenty-eight, with the aid of an open exhibitor.

He attended Maxwell's lectures in 1878 and 1879, the last two years of Maxwell's life, and worked in the Cavendish Laboratory on electrical resistance standards. He obtained a first class in the Natural Sciences Tripos in 1880 and became lecturer in applied mechanics in the new University engineering laboratories. He was made a fellow of St John's in 1882. After a short time at Nottingham, where he held the professorship of physics, he returned to London to start a consulting practice in 1882. In 1884 he was invited to become the first professor of electrical engineering at University College, and he occupied this chair for forty-one years, the inaugural period of the electrical age.

Fleming began his consulting career at the age of thirty-three by becoming adviser to the Edison Telephone Company and continued with it after it was combined with the Bell Telephone interest. Later, when the Edison Electric Light Co. was formed, he became its adviser on the equipping of generating stations and distribution networks. After the carbon filament lamp was invented, he became the adviser of the Edison and Swan combination, particularly of the photometry of lamps. Later he advised a number of English towns on the adoption of electric light. He was also consulted by the London Electric Supply Corporation when it was installing the Ferranti alternating current system in London. In 1899 he became consultant to Marconi's Wireless Telegraph Company and took part in the design of the Polden Station, the first large wireless station in England. In the course of this work he devised new methods and new instruments for the measurement of high frequency current, and he was the first to demonstrate that the thermionic rectifier could operate at radio frequencies. Thus during many years and in many directions he assisted in the adaptation of revolutionary electrical industries to English conditions, and aided the technical development of many fundamental electrical inventions. As fast as he gathered experience in these new technical developments, he passed it on in lectures to his students and to public audiences. He also read widely the expanding electrical technology and lucidly expressed its essence in his lectures. Some of his lecture courses were published as text-books. Among such books one recalls with gratitude "The Alternating Current Transformer", "The Principles of Electric Wireless Telegraphy", "The Propagation of Electric Current in Telephone and Telegraph Conductors", "Electric Lamps and Electric Lighting".

In the midst of all these applications of science to engineering, Fleming found time and energy for a number of physical investigations—for example, the measurement of the electrical and magnetic properties of materials at the temperature of liquid air. Alto-

gether he wrote more than a hundred research and descriptive papers. He was elected to the fellowship of the Royal Society in 1892 and received the Hughes Medal of the Society in 1910, he was also awarded the Albert, the Faraday and the Duddell Medals, and in 1929 he was knighted.

As a teacher Fleming was superb. He had the gift of arranging his subject-matter attractively and of stating his facts and ideas emphatically. He talked straight on, without digressions, doublings, or repetitions, in a direct current of well-chosen words and rounded sentences. His delivery was very rapid, but his resonant voice and crisp articulation ensured that no one missed a word. Nor did anyone ever complain at his meaning was doubtful, everything was sharply defined. After middle age he became very deaf, but retained all his magic as a lecturer. This deafness, by the way, was utilized by his students when in jubilant mood, on such occasions a stranger passing the door of the lecture room might hear a sudden clamour and its sudden cessation, and if he lingered he would hear the uproar switched on and off at intervals. Inside the lecture room he would have seen that when the professor turned to the blackboard there was pandemonium, and when he faced his class there was silence. The timing had to be as reliable as Fleming was quick in his movements. This alertness was characteristic, even when he was in the middle seventies, one could see his linear figure reading swiftly a populous corridor in the College, intent on a goal, looking neither right nor left, overlooking everybody. Indeed in intellectual as well as in material things, Fleming's main principle of action was, full-speed ahead.

W. H. ECCLES

Dr. David Randall-MacIver, F.B.A.

DR. D. RANDALL-MACIVER, the accomplished chæologist and anthropologist, was born in 1873, and educated at Radley and the Queen's College, Oxford, where in 1896 he obtained a first class in *terce Humaniores*. It had been his youthful ambition to devote himself to the pre-Columbian cultures of America, but as this seemed impracticable, he came easily under the influence of Sayce and Grenfell at Leiden's, and learned the technique of Egyptian excavation with Flinders-Petrie. He was the first holder of the Laycock Studentship for Egyptology at Worcester College (1900-6) and in 1907 directed the Eckley B. Coxe, jun., Expedition of the University of Philadelphia to Egypt and the Sudan, publishing with Arthur Thomson a detailed anthropometric study of ancient Egyptian skeletons.

When the British Association visited South Africa

in 1904, Randall-MacIver was entrusted with a reconnaissance of the 'Zimbabwe' type of ruins in Rhodesia, and his rapid but careful and conclusive excavations on a few typical sites demonstrated their date, and caused some indignation locally when they were published in his "Mediaeval Rhodesia". After some work in the Pennsylvania Museum, he came librarian of the American Geographical Society (1911-14), married an accomplished Virginian lady, and seemed to be settling down in New England. But the War of 1914-18 recalled him to Europe as an efficient intelligence officer in France and in Macedonia—he spoke French, German and Italian with equal facility—and after 1919 he settled in France and devoted himself to the prehistoric antiquities of Italy, to which his attention had been

attracted by another Queen's man, the late T. E. Peet, whom MacIver had sponsored in his early years, and with whom, in a manner, he changed careers, when Peet left Italian prehistory for Egyptology. Peet's "Stone and Bronze Ages in Italy and Sicily" (1909) was a pioneer survey of the earlier periods, Randall-MacIver took up the story in 1924 with a stately volume, "Villanovans and Early Etruscans", tracing through tangled and sometimes passionate Italian publications the main theme of the continuity of native Italian culture, and its gradual transformation by the Early Etruscan, which intruded on its region from the south. In 1927 came a companion study of "The Iron Age in Italy", dealing with the cultures of central and southern Italy, neither Villanovan nor Etruscan, which betray early and increasing signs of intercourse with regions east of the Adriatic.

In this way a new approach was prepared to the residual problem of the Greek colonization, and of the foreign imports which portend the first renaissance of 'Magna Graecia'. To this, Randall-MacIver had intended to devote a third memoir, but his many social and personal interests and the death of his wife in 1931 intervened, all that he left on this subject was a charming book of travel, "Greek Cities in Italy and Sicily" (1931). In 1936, he married another American lady, and on the outbreak of war in 1939 withdrew from Italy to New York, where he was able to do valuable services in the British war organization. There he died on April 30, 1945.

JOHN L. MYRES

Prof. Thomas J. Nolan

THE news of the death of Prof. Thomas J. Nolan on March 12, at the age of fifty-six, came as a profound shock to his colleagues and students.

Graduating in University College, Dublin, in 1909 with the highest honours in chemistry, Nolan commenced research work under the late Prof. Hugh Ryan and was awarded a travelling studentship in chemistry in 1911, his thesis dealing with a research on "The Higher Ketones and Secondary Alcohols derived from the Amides of Palmitic and Stearic Acids". In the autumn of 1911, Nolan proceeded to Geneva and commenced research under Amé Pietet on problems dealing with the "Constitution of Isostrychnine" and the "Application of Methylal in Ring Syntheses". Owing to the illness of Pietet this work was not completed. In 1912 he began research under Prof. Samuel Smiles in University College, London, on the "Isomerism of the Sulphides of β -Naphthol", the results being embodied in a series of five papers in the *Proceedings and Transactions of the Chemical Society*, London. In 1913, Nolan worked under Zimcke in the University of Marburg and published in *Liebigs Annalen* a communication entitled "Salpetersäurechinitrol aus 3 5 6 Trichloro-o-Kresol und Umwandlungsprodukte". His most distinguished work at this period was carried out in the Kaiser Wilhelm Institut in Berlin, where Willstätter was engaged on his classic investigations on the colouring matters of flowers and fruit. Under Willstätter's direction Nolan succeeded in isolating the pigments of the rose and peony in a pure condition and establishing their constitution. The outbreak of war in 1914 terminated these researches, and he returned to Dublin and was awarded the D.Sc. degree of the National University.

During 1915-25, Nolan was engaged as research chemist to Messrs Nobel's Explosives Co., Ltd., during which period he carried out many valuable researches. In 1925 he returned to Dublin to become assistant State chemist and afterwards State chemist, a post which he held until his appointment in 1932 as professor of chemistry in University College, Dublin.

Much of the research which Nolan carried out during the past thirteen years was directed towards the investigation of the chemical constituents of lichens found in Ireland. In this very difficult field he was the first to isolate a chlormated depsidone, gangaleoidin, and had gone far towards establishing the constitution of this and other organic substances containing chlorine, which are found in lichens. More recently, he had isolated two nitrogenous constituents in the lichen *Lecanora epanora*.

Among his many activities Nolan served on the council of the Chemical Society, London, during 1926-29. He was chairman of the Board of the

Industrial Alcohol Factories established by the Irish Government, member of the Irish Industrial Research Council and during the emergency created by the War his advice was frequently sought and highly valued both by the State and industrialists.

Nolan was an inspiring teacher, a loyal and undemanding colleague, a staunch friend and a chemist of the highest calibre. His death at the height of his powers is a grievous loss to chemistry and to his University.

JOSEPH ALGAR

We regret to announce the following deaths

Prof. A. Fersman, the distinguished Russian geologist and mineralogist, aged sixty-one.

Sir Martin Forster, F.R.S., during 1922-23 director of the Indian Institute of Science, Bangalore, died May 24, aged seventy-two.

Mr. G. C. Robson, formerly of the British Museum (Natural History), where he was in charge of the collection of Mollusca, on May 17.

NEWS and VIEWS

Geology at the University of Sheffield

Prof. W. G. Fearnside, F.R.S.

Not a few of the younger generation of geologists will learn with surprise of the retirement of Prof. W. G. Fearnside from the Sorby chair of geology at the University of Sheffield. They will have ample ground for wonder whether anyone so patently young can have reached the age at which university professors retire, though the surprise may be lessened by the discovery that he has held the chair since its foundation thirty-two years ago, and consolation will follow the thought that geology still has the promise of his enthusiasm and energy for many years to come. Under McKenney Hughes, as a colleague of Alfred Harker, J. E. Marr, Henry Woods and Gertrude Elles, he commenced his geological career in some of the brightest days of the Cambridge school. It is not surprising that some of his earliest claims to distinction were notable contributions in the Cambridge tradition of Lower Palaeozoic geology, while his characteristic versatility was foreshadowed by his concern at the same time with the teaching of petrology and the collection of quaternary bones. During this period he was a fellow of Sidney Sussex College.

Shortly after his acceptance of the Sorby chair, Prof. Fearnside remarked on one occasion that the time had come to apply the lessons learned in the minute study of the lower Palaeozoic to the problems of the Coal Measures. His publication shortly thereafter of a structural map of the Yorkshire Coalfield laid the foundation of much work by himself and others, which has given greatly increased precision to knowledge of Carboniferous and post-Carboniferous earth-movements and their consequences. Among industrialists and engineers, Fearnside has performed a notable service in demonstrating the value of geology in those spheres, whether concerned with fuels, metals, refractories, bricks or roads. For him there is no 'pure' or 'applied' science. He is equally at home in the councils of the Institutions of Mining Engineers, or of Mining and Metallurgy, or in the presi-

dential chair of the Geological Society or of Section C (Geology) in the British Association. In the Royal Society his work for geology has been outstanding and all will wish that in this and other spheres may long continue.

Major F. W. Shotton, R.

Prof. Fearnside is being succeeded by Major F. W. Shotton, R.E. After a brilliant undergraduate career at Cambridge, Mr. Shotton was appointed to a lectureship at the University of Birmingham, where he worked under Prof. W. S. Boulton and Prof. L. J. Wills. During this time he carried out important work on the rocks of the Coventry district; he also studied the conditions of deposition of the Trias Sandstones with the aid of students from the University of Birmingham, whom he organized into teams for field-work. In 1936 he returned to Cambridge as lecturer under Prof. O. T. Jones and carried out detailed research in the Cross Fell district of the Pennine Chain.

In 1940 Shotton was asked to take an appointment as geologist with the Armies in France, but the next day for the appointment disappeared with the return of the B.E.F. to Great Britain. Shotton was eventually commissioned in the Royal Engineers in the autumn of 1940 and proceeded to the Middle East as geologist on H.Q. staff. Here he carried out excellent work mainly concerned with water-supply problems. In 1943 he was appointed as geologist to the Chief Engineer, Twenty-first Army Group, in succession to Prof. W. B. R. King. During the time before D-day, Shotton was busy studying many problems connected with the Normandy landings, particularly in connexion with the behaviour of various types of beach under different loads, and reaction to shell condition of river banks and bottoms, water supply and suitability of sites for the construction of landing strips for fighter aircraft. Shortly after D-day, he was in Normandy putting the results of this study into practice, and has been with the armies throughout their advance into Germany. During this time,

was justified to the full the appointment of a geologist to the staff of the Chief Engineer. His election to the chair of geology at Sheffield, while enabling him to return to the pursuit and teaching of pure science as a basic study, will enable him to continue to maintain and emphasize the value of geology to all civil engineering practice, as he has done to military engineering in its widest sense.

Chair of Geology at Leeds: Prof. W. Q. Kennedy

DR W. Q. KENNEDY, who has been appointed to the chair of geology in the University of Leeds, is a senior geologist on the staff of the Geological Survey in Scotland. Before joining the Geological Survey in 1928, Kennedy studied under J. W. Gregory in Glasgow and under Niggli in Zurich. As a result of his Continental training, he became one of the first geologists in Britain to apply Fedorov and Sander 'universal stage' technique to the microscopic study of rocks, and early in his career published a translation of Chudoba's text-book on the determination of plagioclase feldspars by 'universal stage' methods. Kennedy has made notable contributions to geological research. In petrology he has dealt with pyrometamorphic ore-deposits, composite lava-flows, the parent magma of the British Tertiary Province and, in conjunction with Dr E. M. Anderson, the origins of basaltic magma. His conception of volcanic and plutonic associations has been acclaimed as a fundamental contribution to tectogenetic theory. Perhaps his most notable work in Scotland is his study of the Great Glen Fault, which led him to infer a lateral shift of some 65 miles along this fracture and to discuss its tectonic and metamorphic implications. His official Survey work with Dr J. E. Richey on the Moine and sub-Moine rocks of the Morar district has also produced notable results in Highland stratigraphy and tectonics.

Prior to the opening of the new Geological Museum in London in 1935, Kennedy spent a year or two in London preparing the ground-floor exhibits illustrating volcanicity and glaciology. During the war, he has been concerned with economic investigations on Scottish feldspar mica, iron-ore, l-shale, mineral oil, natural gas and dolomite. His re-war discovery of a valuable muscovite deposit in the Scottish Highlands has proved to be of national importance.

University Development at Birmingham

THE University of Birmingham has launched an appeal for £1,500,000 for purposes of development, and promises of £638,636 have already been received. Outstanding items in the proposed scheme are £100,000 each for four additional halls of residence (three for men and one for women), £200,000 for a new library, £170,000 for new laboratories for mechanical and electrical engineering, £150,000 for buildings at Edgbaston to house the Faculties of Arts, Commerce and Law, and central administration, and £100,000 each for the endowment of chairs of geography and electronics. In the words of the Vice-Chancellor, Dr. Raymond Priestley, "Men and women to must guide and control a great industrial people, and the experts who are to be the spear-point of scientific industry, are best educated within sight and sound of the factory and the market-place. We are moving forward into a world in which technical development will take place at an accelerating rate.

To equip ourselves for the competition we shall have to face in order to maintain our standard of living—if not our very existence—in the post-war world involves mobilization of the skill and talent of the whole people, together with development of character, to put the programme through. We need to combine the best features of the older universities with the specialities of the new that are in closer touch with the industrial world. Given the will and the apparatus, there is nowhere that this could be done better than here in Birmingham."

Industrial Ophthalmology

THE Institute of Ophthalmology, Royal Eye Hospital, St George's Circus, London, S E 1, proposes to devote a considerable proportion of its funds to industrial ophthalmology. In view of the absence of any co-ordinated work in this field, it is felt that a national survey of workers, and of work already accomplished, is a necessary preliminary to the undertaking of research on any specific aspect of this very extensive subject. The Institute therefore invites those who have routine experience in any branch of industrial ophthalmology, or who have undertaken original work bearing upon it, to communicate with the Institute stating briefly their experience and defining the aspect of the work with which they are most familiar—medical supervision, safety, lighting, industrial psychology, etc. It is the Institute's policy to promote the investigation of industrial ophthalmic problems in the districts in which they arise. It is hoped that those replying to this request will be willing to co-operate in their own areas and in their special fields of interest and experience as the national scheme develops. This invitation is extended not only to individual workers, but also to research and other organizations concerned. The funds will be distributed on the recommendation of the Scientific Executive Committee in the form of grants for approved work. The Committee proposes, initially, to support, co-ordinate and publish work undertaken throughout Great Britain.

Industrial Data in Britain

ACCORDING to an article in the *Board of Trade Journal* of May 26, 1945, the Board of Trade is to undertake, through the regional research sub-committees formed as adjuncts to the Distribution of Industry Committees, the collection and assembly, on a continuing basis, of a wide range of factual data required for distribution of industry purposes covering every locality in Britain. In making such surveys the Board of Trade will make the fullest use of information on industry already accumulated by the supply Ministries and by the Ministries of Labour and Town and Country Planning. It is also intended to take the fullest advantage of local knowledge by consultation with non-official bodies, whether universities, local authorities or industrial groups. By these means the Board of Trade should be made conversant with the industrial problems of all parts of the country and equipped to provide the industrial world with an information service to help individual firms in making decisions on the location of new factories.

Astronomical Observatory of Madrid

THE *Anuario* for 1945 of the Madrid Observatory has been prepared on a plan similar to that of the preceding issues, with some slight modifications intro-

duced in the year-book for 1944. Observations and records of solar activity during 1944 have continued, and the results, together with those made at the observatories of Valencia and Cartuja, have been sent to the International Bureau at Zurich. Time signals have been carried out, and photographs of comets and planets, occultations of stars by the moon and other notable phenomena have been included in the programme. *Boletín Astronómico*, 2, No 10, contains the results of observations of sunspots and prominences in 1938 and the positions of a number of comets observed in 1941 and 1942, while *Bol Ast*, 3, No 1 contains the results of solar observations made in 1939 and 1940, including also those made during the latter year at Valencia. Repairs were started in the Observatory, those to the astrographic pavilion being completed, and the installation of the instrument and the new cupola to house it will allow the renewal of observations. At the end of the year-book there is an interesting section containing 72 pages with the title "El Sistema Galáctico", by José María Torroja Menéndez. This provides a very useful summary of our knowledge of the galaxy.

Belgian Scientific Delegates in Britain

A THIRD group of Belgian professors representing the Belgian Fondation Universitaire is now visiting Britain for a fortnight at the invitation of the British Council. They are visiting universities or research institutions in London, Reading, Oxford, Cambridge, Newcastle, Aberdeen, Edinburgh, Liverpool and Greenwich, and the ICI works at Billingham. The delegates are Prof F. Van den Dungen, professor of analytical mechanics, University of Brussels, Prof A. Michotte van den Berck, professor of experimental psychology, University of Louvain, Prof A. Gratia, professor of bacteriology, University of Liège, Prof J. A. H. Rodham, director of the Institute of Tropical Medicine, Antwerp, Prof E. J. M. P. Mertenis, professor of industrial chemistry, University of Louvain.

Cambridge Summer School in X-Ray Crystallography

A SUMMER school in X-ray crystallography will be held again this year in the Department of Mineralogy and Petrology, and in the Cavendish Laboratory, Cambridge, during the two weeks September 3-14. The school is conceived as a means of providing an introduction to the fundamental theory, methods and techniques of X-ray diffraction, so that those whose researches, whether in the universities or in industry, lie in the field of physics, chemistry, metallurgy, mineralogy or biology may be able to recognize in their own work the types of problem to which these methods may with advantage be applied. The greater part of the course will be devoted to practical work on the interpretation of the various types of X-ray photograph. For the last two days, however, alternative lectures and demonstrations will be offered in two sections. One section will include further steps, theoretical and practical, in the study of crystal structures, while in the other some applications of the earlier work of the course to metallurgical problems will be studied. A detailed syllabus and form of application for admission may be obtained from Mr G. F. Hickson, secretary of the Board of Extra-Mural Studies, Stuart House, Cambridge, to whom the completed application form should be returned not later than June 23, 1945.

Announcements

THE following appointments in the Colonial Service have been made: W. J. Kinghorn, to be director of agriculture, Bermuda; Miss B. Y. Campbell, to be nutrition officer, Trinidad; T. A. Russell, director of agriculture, Bermuda, to be agricultural officer, Nigeria; N. M. Wight, agricultural officer, Tanganyika, to be senior agricultural officer, Jamaica.

At the anniversary meeting of the Linnean Society of London held on May 24, the following were elected officers for the year 1945-46: *President*, Mr A. I. Cotton; *Treasurer*, Colonel F. C. Stern; *Secretaries*, Dr B. Barnes (botany) and Dr Malcolm A. Smith (zoology); *New Members of Council*, Mr A. H. Alston, Prof T. A. Bennet-Clark, Dr F. C. Fraser, Dr H. S. Holden and Dr S. M. Manton.

At the annual general meeting of the Physics Society on May 23 the following were elected or re-elected for 1945-46: *President*, Prof D. Brunt; *Vice-Presidents*, Sir Edward Appleton, Prof Chapman, Prof H. T. Flint, Prof N. F. Mott; *Hon. Secretaries*, Mr J. H. Awwbery (*Papers*), Dr W. Jevons (*Business*), *Hon. Foreign Secretary*, Prof E. N. da Andrade; *Hon. Treasurer*, Dr C. C. Paterson; *Hon. Librarian*, Prof L. C. Martin; *Council*, Prof J. Bernal, Dr B. Chalmers, Dr C. H. Collie, Mr E. Davies, Prof G. I. Finch, Dr W. B. Mann, Mr A. Philpot, Dr D. Roaf, Prof H. R. Robinson, Dr J. Shaw, Dr W. S. Stiles, Dr W. D. Wright. The officers of the Colour Group for 1945-46 are: *Chairman*, Dr R. K. Schofield; *Secretary*, Dr W. Wright; and of the Optical Group, *Chairman*, Ins. Capt. T. Y. Baker; *Secretary*, Mr E. W. H. Selwyn.

At the annual general meeting of the Illuminatus Engineering Society held on May 15 the following were elected officers for the forthcoming session: *President*, Mr H. C. Weston; *Vice-Presidents*, Mr Howard Long, Mr H. E. Chasteney and Mr J. Waldram; *Hon. Treasurer*, Mr N. V. Everton; *Hon. Secretary*, Mr J. S. Dow; *Members of Council*, Mr J. N. Aldington, Mr M. G. Bennett, Dr W. Hampton, Mr A. G. Higgins, Mr J. S. Preston, Mr A. J. Pashler, Mr E. B. Sawyer, Dr W. S. Stilwell and Dr W. D. Wright.

At the meeting of the Board of the Finney-How Research Foundation, Inc., on March 2, fellowships were renewed for the third year for Dr Nelicia Marx for the second year for Drs Muriel Virginia Bradl and Margaret Aston Kelsall, and a new fellowship awarded to Dr Elizabeth Cavert Miller, to work at the University of Wisconsin. Applications for fellowships for 1946 must be made to the Foundation Medical and Chirurgical Faculty Building, 12 Cathedral Street, Baltimore, Md., U.S.A., before December 1945.

THE Leeds Branch of the Association of Scientific Workers will hold an open conference on "Science and Education" at the Philosophical Hall, C. Museum, Leeds, on June 9, at 2.30 p.m. It is hoped to discuss the teaching of scientific method in elementary education, the comparative value of science and the humanities in general education, a curricula for specialist technicians. Sir Robt. Watson-Watt will open the discussion and Dr W. Astbury will preside. Tickets of admission (price 1/-) can be obtained from the honorary secretary of the Leeds Branch of the Association of Scientific Workers, 95 Holywell Lane, Glasshoughton, Castleford.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

Structure of Alginic Acid

THE following is a short account of work completed a matter of two years ago; but publication at the time was forbidden. It was carried out in connexion with the production of rayon from seaweed described by Speakman and Chamberlain¹, and for the preparation of the fibres I am indebted to Dr. Chamberlain.

The alginic acid fibres finally arrived at gave at ordinary humidity a well-oriented X-ray diagram that could be evaluated without ambiguity. At this humidity the unit cell contains four mannuronic acid residues and perhaps four water molecules—it is difficult to be more definite than this, because both inter- and intra-crystalline water is present, and the density of the crystallites is not necessarily the same as that of the fibres as a whole; if we assume that it is, then the intra-crystalline water approaches four molecules per cell. Through the cell two chain-molecules run in opposite directions, one through the corners and the other through the middle of the (10) face, as in cellulose. On drying the fibres intensively the a -axis decreases and the X-ray pattern deteriorates; but the change is completely reversible on re-exposure to the atmosphere. From X-ray measurements the cell dimensions are: $a = 7.7$, b (fibre axis) $= 8.7$ A., $c = 10.6$ A. The space-group is probably Q^3 ($P2_12_12_1$), but it approximates Q^4 ($P2_12_12_1$). The dry density was found by Dr. Chamberlain to be 1.627 gm./c.c.

The evidence from X-ray analysis is all in favour of the pyranose formula for alginic acid² [see also p. 655]:

and interest centres therefore in why the period along the fibre axis should be 8.7 A. instead of the 10.3 A. and in cellulose. There is no reason from the properties of the fibres to think that the chain of β -D-mannuronic acid residues is not stereochemically fully extended, so presumably the cellulose and alginic acid configurations are alternatives derivable from common postulates. As already indicated in a previous communication on the structure of cellulose³, to find this to be so: there is no need to depart significantly from the usual interatomic distances and bond angles, and the Sachse strainless ring in the so-called 'armchair' form constructed to these dimensions suffices for both cellulose and alginic acid. The difference lies simply in this, that there are two possible directions of the bonds joining C₁ and C₄ to the glucosidic oxygens, and the flatter arrangement is found in cellulose and the other in alginic acid. The idea will be clear from the skeleton models illustrated. Taking the carbon bond angle to be tetrahedral, the oxygen bond angle to be 110°, C—C = 1.54 A., and C—O = 1.42 A.⁴, the calculated fibre period for cellulose comes to 10.3 A. and that for alginic acid to 8.7 A., as compared with 10.3 A. and 8.7 A. given by X-rays.

SKELETON MODELS OF THE CHAIN CONFIGURATION IN CELLULOSE AND ALGINIC ACID.

It is important to realize that the two configurations are not independent: one is not the prerogative of cellulose and the other of alginic acid, for in principle either may pass over into the other by intramolecular oscillation, as is easily seen on manipulating a model made with flexible bonds. The cellulose we know has one form and the alginic acid we know has the other, but it is conceivable that conditions, or derivatives, may be found for either that favour a change-over. For example, it has rather come to be expected that cellulose derivatives will be found always to have a fibre period that is a multiple of 5.15 A., and on this basis the 25.6 A. period of trinitro-cellulose has been assumed to correspond to the length of five residues; but it is not impossible that it corresponds actually to six residues in the alginic acid configuration. Similar remarks may apply to the 38.3 A. period given by α -camphor nitrocellulose-I⁵, which on current ideas would appear to correspond to $7\frac{1}{2}$ residues.

Another point worth emphasizing is that the two kinds of chain just described are not specially a consequence of the β -linkage. Our present fibre photographs of pectin are not as well resolved as those of alginic acid, but there can be little doubt that they are of the alginic acid type. But pectin is based chiefly on chains of α -galacturonic acid residues: the respective dispositions of hydroxyl groups in cellulose, alginic acid, and pectin are such that to produce the same result requires the β -linkage in the first two but the α -linkage in the last.

These findings, taken in conjunction with those of Cox and his collaborators⁶, go far towards establishing that the structural scheme for sugars formulated by Haworth and his school finds three-dimensional expression in the various configurations that are derivable simply by use of atomic distances and angles found to hold in less complicated aliphatic molecules, as, indeed, the sugar chemists themselves have long supposed. It is of great interest now to try to identify other theoretically possible examples besides the two discussed here, and also to determine what it is, in terms of physico-chemical conditions and the nature and arrangement of side groups, that decides the arrangement found in cellulose on one hand and that in alginic acid and pectin on the other. With

this end in view the investigation is being resumed with other polysaccharides.

I wish to record my thanks to Prof. J. B. Speakman and Dr. N. H. Chamberlain for supplying all the alginic acid fibres examined, to Drs. F. O. Bell, K. M. Rudall and M. M. Davies for much help on the experimental side, and to Prof. E. L. Hirst and his colleagues for guidance among the chemistry of the sugars.

Residual Films of D.D.T.

IN the course of an investigation into the toxicity to houseflies of films of the insecticide D.D.T. deposited upon an absorptive type of wall-board, some observations have been made which may help to explain certain results obtained in field and laboratory tests by other workers.

Pieces of wall-board were sprayed with various concentrations of D.D.T. in 'Pool' burning-oil to give equal deposits of D.D.T. per unit area. After four days at 27.5° C. and 60 per cent relative humidity, flies were confined on the treated surfaces under petri dishes. From the data for toxicity to flies it was clear that, within the limits of the experiment, the highest toxicity was obtained from a given quantity of D.D.T. by applying it at a high concentration.

When the same samples were tested four weeks after treatment, those with the highest concentrations of D.D.T. had increased strikingly in toxicity. Microscopic examination revealed that, on those samples to which the D.D.T. had been applied in high concentration, the areas exposed to flies at the first test had become thickly carpeted with minute crystals of D.D.T. Further investigation has shown that D.D.T. has a great tendency to supersaturate or supercool, this tendency being greater with crude than with pure D.D.T. and greater when the solvent is 'Pool' burning-oil than acetone. Movement of the confined flies is sufficient mechanical agitation to induce crystallization of the relatively poorly toxic gum-like residue, a phenomenon which can also be initiated with a soft paint-brush. If the surface remains undisturbed, crystals do not form for at least several weeks and much of the potential toxicity of the D.D.T. residual film remains latent. The data supporting these observations will be reported more fully later.

Activated Adsorption of Hydrogen in the Neighbourhood of the Curie Point

IN catalytic phenomena the ferromagnetic metal (iron, cobalt, nickel) possess a special interest. On the other hand, it is also known that adsorption phenomena are closely connected with catalysis. In continuation of systematic work carried out during recent years in this laboratory on adsorption phenomena, we measured the adsorption of hydrogen on nickel sheets between 200° and 400° C. The nickel is thoroughly cleaned by washing it successively with hydrogen and pumping off for several hours at 600° C. at a pressure lower than 10⁻⁶ mm. Special care is taken with the purification of the hydrogen. The measurements have been made with pressure up to 1 cm. It is found, first, that the equilibrium is very rapidly reached (30 sec.); secondly, adsorption increases with increasing temperature; thirdly, in the neighbourhood of the Curie point (358° C) the isobars show a very pronounced discontinuity (see graph).

Chevenard¹ and Williams² found also by means of measurements on the thermal expansion coefficient of nickel some discontinuities at the Curie point. These discontinuities are, however, too small to explain the phenomena observed by us. It is known that activated adsorption is connected with the electronic state of the metal, and at the Curie point this state undergoes some characteristic modifications.

Finally, our measurements on adsorption isotherms revealed partial reversibility for the adsorption.

A detailed report on these measurements will be published in the *Annales de Physique* (Paris).

Elastic Recovery in Capillary Flow

IN a previous communication¹ the non-Newtonian behaviour of certain visco-elastic materials, including rubber solutions and soap-thickened mineral oils, was discussed. Experiment had shown that when such liquids flow through a capillary there is a loss in pressure at the tube entrance followed by a uniform fall in pressure down the remainder of the tube. This was shown to be large, particularly at high stresses, and if expressed in the form of an end correction, sometimes amounted to as much as fifty micrometers. The effect was attributed in a general way to the elastic nature of the material since it did not occur in Newtonian liquids or solid-liquid suspensions. In addition, this 'elastic end effect', as it was termed, was found to be related to the recovery or swelling of the column of liquid issuing from the capillary. Elastic recovery normally starts at the actual capillary end, but it has now been observed that at high stresses, corresponding to velocities of one or two metres per second, recovery is delayed. The delay becomes more pronounced if velocity is increased further, as the accompanying photographs show. All the materials and concentrations so far studied show this phenomenon.

7 m./sec. 5.5 m./sec.
Mean velocity.

It was also found that with certain solutions the onset of this delay coincided with an unmistakable 'kink' in the flow curve, indicating a sudden increase in the rate of flow.

It is not possible at this stage to state the exact cause of these anomalies—the delay in recovery and sudden increase in the flow-rate—but several explanations are possible. It might, for example, be due to slip at the tube wall. A more likely explanation, however, involves the question of time. At low velocities recovery is very rapid compared with the downward movement; but at high velocities the liquid may not be

able to make any appreciable recovery until it has moved some distance from the tube; hence the delay in the appearance of the swelling.

With normal recovery the swelling is usually very rapid (cf. Fig. 2¹) and it seems possible that this may act on flow immediately inside the tube, producing a small 'back pressure' tending to restrict the flow. This restriction would be removed when recovery took place well away from the capillary, and we could expect a sudden increase in the flow-rate at the transition. This idea seems to be supported by the fact that the 'kink' is apparent in precisely those materials which show a relatively large recovery (and consequently a large entrance loss); in cases where recovery is relatively small, no appreciable 'kink' occurs.

Internal Waves in the Sea

I AM just reading with great interest the important and excellent work by H. U. Sverdrup, M. W. Johnson and R. H. Fleming, "The Oceans: their Physics, Chemistry and General Biology" [Prentice-Hall, Inc., New York, 1942. See p. 652 of this issue of *Nature*]. I should like to direct attention to a lapse which I am rather anxious to have pointed out. On page 592 the first observation of internal waves in the sea is attributed to Helland-Hansen and Nansen. The fact is that such waves were discovered in the Great Belt two years before by the nestor of Swedish oceanographers¹, the late Otto Pettersson—well known as the originator of the international organization for marine research—and he also proved their tidal periodicity. Furthermore, on page 600 reference is incidentally made to observations of internal waves in a Swedish fjord which Otto Pettersson is said to have carried out "during 2 months of 1909". As a matter of fact, these observations were continued over several years², and—although particular theoretical conclusions which Pettersson inferred are open to serious criticism—the observations themselves are in their method by far the most exhaustive ever made.

These comments may seem to be of minor importance, but since internal waves have, of late, attracted the intense and increasing interest of oceanographers, and since Otto Pettersson himself was from the first aware of the importance of his discovery and took particular interest in it, I think we owe him the justice of acknowledging his priority, at the same time as we recognize the important contributions of Nansen and Helland-Hansen.

V. WALFRID EKMAN.

Gostad, Stockaryd,
Göteborg.

¹ Pettersson, O., "Strömstudier vid Östersjöns portar", *Svenska Hydrografisk-biologiska Kommissionens Skrifter*, 3 (1907). Also in "Ueber Meeresströmungen", *Veröffentlichungen des Instituts für Meereskunde* (Berlin, 1908).

² Pettersson, O., "On the Occurrence of Lunar Periods in Solar Activity and the Climate of the Earth", *Svenska Hydrografisk-biologiska Kommissionens Skrifter*, 5 (1914).

IN making the statement on page 592, to which Prof. Ekman refers, "that the first observations of short-period variations which indicated the existence of internal waves were discussed by Helland-Hansen and Nansen (1909)", the authors have in mind the short-period variations observed during the 1893-96 voyage of the *Fram*. Nansen realized that they might be due to waves at the boundary between waterstrata of different density, but it was not until 1909 that he and Helland-Hansen, persuaded by their 1900-4 observations in the Norwegian Sea, were convinced of the reality of internal waves.

In the meantime, Otto Pettersson had observed the rise and fall, with tidal periodicity, of the boundary surface between the poorly saline water from the Baltic Sea and the more saline undercurrent from the Skagerrak. Helland-Hansen and Nansen did not acknowledge this contribution although they were aware of it (p. 239; 1909).

Technically, at least, Pettersson's claim for prior discovery is well-founded, but it is obvious that the question was one under wide discussion at the time, and the Norwegian oceanographers would make a strong claim. It is quite possible that Prof. Ekman's own work on 'dead water', published in the results

of the 1893-96 expedition, played a great part in suggesting the correct explanation.

Oceanography has advanced too rapidly in the twentieth century to allow its text-books to include an adequate treatment of historical aspects. It would be a very good thing if a history of the subject could be written, while authorities whose basic contributions have been appearing since late in the nineteenth century can, happily, still be consulted.

Biliverdin as a Pigment in a Fish

In *Belone belone*, the garfish, the bones, scales and fin rays are of a bright green colour. The chemical nature of this well-known colouring matter has long remained unknown. It cannot be extracted from the tissues in which it occurs by any organic, or neutral, weak acid or alkaline inorganic solvent. But in stronger bases the green scales show a particularly clear transition to yellow, which can be turned back to green again in acids. In at least ten per cent alcoholic hydrochloric acid, the green colouring matter quickly becomes a blue-green in solution and can be separated with chloroform. It gives a clear Gmelin reaction and shows in its insolubility all the typical characteristics of biliverdin.

Thus, a gall pigment has been found in invertebrates for the first time, together with other pigments, as a colouring matter of the integument.

Genetics of Woodlice

I POINTED out recently¹ that my last brood of *Armadillidium vulgare* (Latr.), var. *rufobrunneus* Clge., nearly all died. Of the previous brood, the result of a cross between a female of *rufobrunneus* and a male of Howard's type *D*, I obtained the following interesting result. A brood liberated on October 26 consisted of 40 female *rufobrunneus* and 27 males of type *D*. Most of the male specimens have been consumed by the females of *rufobrunneus*. I secured, however, three females impregnated by one of the males of type *D*, and from these I have obtained three broods. All the specimens appeared to be sickly and most of them died.

Later, I placed a specimen of *rufobrunneus* from the brood A with a male specimen from brood C. The result was a brood of 52 females referable to the variety *rufobrunneus*, as shown below:

If we compare these two series of experiments (*Nature op. cit.*), and the present record, the following facts seem clear.

(1) That the female of the variety *rufobrunneus* crossed with the male of Howard's type *D* in the first generation produced more females than males in the second generation, there were more male than females, and in both cases all were referable to type *D*. In the third generation we find no specimens referable to type *D*; all belong to variety *rufobrunneus* and all are females.

(2) In the second experiment, described above the variety *rufobrunneus* dominates in three separate broods and the bulk of the progeny were female namely, 97 females and 16 males. In the final brood all the specimens were referable to the variety *rufobrunneus* ♀.

(3) It would appear from these experiments that the variety *rufobrunneus* was a dominant form, and while the type *D* makes its appearance, in only one instance did it exceed the number of females.

Colour and Growth of Hair in Rabbit

HADDOW *et al.*¹ have recently reported that the growth of hair on the rat appears to take place as a series of waves symmetrically disposed about the longitudinal axis. They support this view by studying the disposition of a flavin dye, which, after injection, colours the hair of albino rats in a pattern corresponding to the most rapidly growing hair. They record the areas of regeneration of depilated hair and show that the blood capillaries are most dense in the areas of rapid growth.

Rabbits have been depilated here for many years in order to study either vaccinia lesions or the behaviour of 'diffusing factor' (hyaluronidase). Observations made concerning the growth of hair on the rabbit may be of interest.

Hair growth on the rabbit appears to follow a similar course to that reported for the rat. In rabbits with coloured hair the waves of rapid growth are disposed symmetrically about the longitudinal axis and can be observed on the depilated animal as raised coloured areas varying from about 0.5 to 5 cm. wide and usually stretching from the ears to the hindquarters. Close examination of these areas shows that they are coloured because they contain pigment in the hair shafts. When the hair has ceased active growth the proximal half of the shaft is white, pigment being restricted to the distal part. Hence the skin regions of restricted growth appear white. Varieties of rabbit such as the Flemish Giant have hair, each shaft of which has bands of different colour. The bands always appear in the same order, and hence by noting the colour of the shafts just emerging from the skin an estimate may be made of the direction of the growth wave. The younger hair is always the ventral edge of the wave, and from this it is deduced that the waves spread from the dorsal to the ventral surface of the animal. In albino rabbits rapid growth of hair seems to occur in raised hyperaemic areas in which the pink colour suggests dilatation or abundance of skin vessels. These areas are 'spongy' if injected with a needle. Hyperaemia and thickening of the skin in these areas of rapid hair growth are always more pronounced on the ventral edge, the whole area appearing as an escarpment facing downwards. In adult animals these waves of hair grow

usually occur in spring and autumn. Young growing animals show areas of rapid hair growth more frequently and do not show the same seasonal incidence. No such areas have been noted on depilated guinea pigs.

Hair growth on the rabbit may be artificially modified by agents that induce localized hyperaemia. For example, in animals which have recovered from vaccinia lesions the hyperaemia engendered by the vaccinia pox persists and a strong growth of hair frequently occurs exactly over the sites of the healed vesicles. This hair appears to be quite normal except that it is surrounded by relatively bare areas in which no vesicle, and therefore no hyperaemia, has occurred. Similar growth takes place after the intracutaneous injection of small doses of diphtheria toxin.

These observations correlate well with the experimental results of Haddow *et al* that "by far the greatest density of capillaries occurs in those positions which correspond to the advancing edge of the growing hair—" and that "it is likely that the pigment (the flavin dye) enters growing areas partly because these are the only ones in sufficiently active interchange with the general circulation." From the observations on the rabbit reported here it appears likely that both rapid growth and natural pigmentation of the hair shaft in this animal are correlated with local increased blood supply to the hair follicles.

Feeding Twitch Rhizomes as an Alternative to Hay

TWITCH, or couch, grass (*Agropyron repens*) is among the common weeds which are difficult to eliminate. It is widespread, and persistent 'cleaning' of the soil seldom eliminates the whole stock, even more serious is the widely dispersed pest in hedge banks and other uncultivated plots. It is not only distributed by air-borne seeds, but it also extends rapidly by the creeping roots or rhizomes.

The roots or rhizomes are palatable and pigs are known to be fond of them. They also proved palatable when fed to domestic rabbits.

The chemical composition of dried roots of twitch showed them to be somewhat similar to meadow hay of good and lower-grade qualities, the rhizomes contain less fibre and somewhat less protein and mineral matter but, compared with cereal straw, rhizomes appear to be superior in protein and carbohydrate content.

COMPOSITION¹ SHOWN BY ANALYSIS

	Dry Matter	Protein	Oil	Carbohydrates Sol	Fibre	Ash
twitch rhizomes (dried)	85.0	5.0	0.6	56.5	19.8	3.1
meadow hay, poor	85.7	7.5	1.5	38.2	33.5	5.0
" " good	85.7	9.7	2.5	41.0	26.3	6.2
" straw, winter	86.0	1.9	1.5	43.1	34.6	4.9
" " spring	86.0	2.9	1.9	42.4	33.9	4.9

The shortage of hay supplies, following the 1944 drought during the growing season, has accentuated the need for hay substitutes^{2,3}.

Several palatability tests proved that rabbits ate the rhizomes more readily than rough grass hay and was therefore decided to carry out a small feeding trial.

Feeding Rhizomes Eighteen resting female rabbits of Bevers type were divided into two similar groups. All but one in each group were yearlings, the other was approximately three years old. The basal maintenance diet consisted of succulents, green-food (of variable quality, according to seasonal supply, but similar for both groups) and/or roots, supplemented by meal mash containing minerals and cod liver oil. Water was provided. The control group received rough grass hay, cut from poultry runs, while the other group was given dried twitch rhizomes of common couch or twitch grass.

The hay supply consisted of hard fescue and tall oat grass, cocksfoot, smooth-stalked meadow grass, foin, Yorkshire fog and a trace of clover. The species predominance was in that order.

The rhizomes were harrowed out and then forked over and air dried. They were relatively clean in appearance and were stored and fed in this state for the first eighteen weeks of the trial. During the remaining period, freshly dug roots were used, but owing to excessive soil adhering to them they were washed and air dried, although the time of year (November) precluded complete drying of this supply.

During a preliminary week, it was found that average daily consumption rates were, hay 0.75 oz and rhizomes 1.06 oz. Therefore the supply was restricted averaging 0.7 oz per head per day in each group.

Throughout the period of feeding unwashed and dried rhizomes, this group maintained a slight advantage in live weight over the controls fed on hay. After the change-over to freshly dug rhizomes the twitch group continued to give slightly heavier body weight in all but three weeks in spite of the reduced dry matter intake.

At the conclusion of twenty-five weeks of feeding twitch grass rhizomes as a substitute for hay the average live weight had increased in the hay group by 3.70 oz, and in the rhizomes group, 4.91 oz.

The condition of the animals was good, although they were moulty at the commencement, and improved as they moulted through. Health was excellent, with one exception in each group. An older one in each group died in the tenth week on twitch, and eighteenth week on hay. The respective post-mortem examinations by the veterinary officer revealed nephritis (twitch) but examination for sand was negative, and abscesses on the spleen and liver (hay). The rest of the stock remained free from symptoms of disease. The coats appeared to be slightly silkier on rhizomes than hay at the end of the seventh week, but after the feeding of freshly dug rhizomes the tendency appeared to be reversed. While there were differences between individuals within groups, the differences between groups were not outstanding, and appeared to depend largely on the stage of the moulting process.

Summary Air-dried twitch grass rhizomes, either washed or otherwise, were found to be palatable to domestic rabbits. The rhizomes were less bulky than an equal weight of rough grass hay and were eaten more quickly, and they proved to be a satisfactory substitute for hay when fed in maintenance rations for 175 days.

Non-luminous Flame Gases

PROF W T DAVID and his co-workers have published a moving-film record of the passage of flame gases along a glass tube¹. Such records have frequently appeared elsewhere², but the explanation given by the writers of the letter, namely, that "the flame gases, although luminous after the early stages of flame-front travel from the igniting spark, suddenly become non-luminous after further travel (due apparently to a sudden change in the mode of combustion in the flame-front)" is a mis-reading of the photograph.

The apparent luminosity persistence after the spark has passed, and behind the flame front, is due to the elongation of an expanding ellipsoidal shell of flame, so that the later luminosity is that of freshly ignited gas. A detailed description and explanation of such records was first published in 1928³.

An Illusion of Size

If one looks at two nickel threepenny bits, a brand new one and a mat old one, with reduced illumination, the old one appears considerably bigger. The difference is striking if the illumination is correctly chosen. Out of fifty people, two only did not see the phenomenon immediately, even those two recognized it when the experiment was repeated. Older people realized it quicker than younger ones. Colour does not play any part, as the same difference is recognizable with shillings.

The phenomenon is obvious with a neutral or dark background, but is not provoked, or it may be inverted, when the two objects of different light value are viewed against a white background. Here the new coin sometimes appears bigger than the old one, when light is reduced.

The only explanation of the effect which I can offer is as follows. The old coin appears fogged when light is reduced, while the shining new piece of metal reflects light and is seen sharply. We are accustomed to linking a greater distance with a fogged object and therefore to over-estimate its size. Thus the moon seen through thin clouds appears bigger than a clear shining one, and misty hills seem to be at a greater distance than those sharply outlined and the size of the latter is correspondingly undervalued (Luckiesh¹).

This explanation is supported by the fact that the difference of size is more impressive after some seconds, as the phenomenon is psychological and not

a purely physical one. If we use a white background the experiment fails. It seems that there is not sufficient light reduction to create the adequate dimness of the old coin, while irradiation may interfere in the case of the new one. Using Ostwald's colour papers as background, I found that variation of colour does not influence the intensity of the size illusion but that different greys of the *A - P* series produce it sufficiently, the darker greys being no better than the middle ones.

Avoidance of Obstacles by Bats

MR OLIVER G PIKE, in his interesting article on bats in *Nature* of January 27, suggests that these creatures avoid obstacles in the dark by means of "a sense of which we know little, and to which it is very difficult to give a name, but which appears to be connected with the 'earlet' and the 'horseshoe'". These organs, *combined with their keen sense of hearing*, assist them to dodge all obstructions, and to find insect food while flying in the dark" (my italics).

The phrase in italics contains the key to the problem. Recent work in America by Galambos and Griffin^{1,2} has shown that the mechanism of obstacle avoidance by bats depends on their utterance of supersonic cries, the echoes of which from insect prey or obstructions are picked up by the cochlea. The 'stereoscopic hearing' resulting from central analysis of these supersonic echoes compares very favourably with binocular vision. It is interesting to reflect that a biological application of principle now widely used for the detection of military target has thus been revealed.

Marine and Other Biological Laboratories

PROF J H. ORTON's article¹ contains certain inaccuracies as regards the status of marine biological laboratories in Scotland. First, the Millport Laboratory is not attached to the University of Glasgow, but is the property of the Scottish Marine Biological Association—an organization parallel with the Marine Biological Association of the United Kingdom to which the Plymouth Laboratory belongs. The Millport Station receives welcome aid from all the Scottish universities, more particularly Glasgow.

Further, it might be pointed out that "St Andrew Nigg" has no meaning. The University of St Andrews owns the Gatty Laboratory at St Andrews, but the former station at Nigg was operated by the Fisheries Board for Scotland and not by the University of Aberdeen.

THE KELP TRADE

By DR V. J. CHAPMAN

Botany School, Cambridge

THE formation of the Scottish Seaweed Research Association last year stimulates one to inquire into the somewhat chequered history of what is now known as the kelp industry. At one time this assumed considerable importance in Europe and afterwards spread to the United States and Japan, the last-named country producing in 1929 some 7 per cent of the world's iodine entirely from seaweeds. The word 'kelp' itself properly refers to the burnt ash of seaweed, but has since been extended to include the living plants.

The beginnings of the kelp industry are associated with the need for soda in the manufacture of glass and the glazing of pottery. Some time in the seventeenth century the kelp industry had its origin in France, and soon became so important that Louis XIV gave the Royal Company of Glass Manufacturers in Paris the sole privilege of cutting annually between certain fixed dates all the suitable seaweed along the coast of La Hague. This had to be revoked because of local agitation among the farmers, who from time almost immemorial had used the seaweed as manure on the land. Its use in this fashion had enriched the coastal lands to such an extent that they were known as the *Ceinture Dorée*.

Soon after the turn of the century the kelp trade began to spread, first to Ireland, thence to Scotland, the Orkneys and to Norway. In Scotland the first cargo left the Hebrides in 1722 and the trade then started to flourish so much that by 1800 Scotland was said to have produced about twenty thousand tons annually. This is probably an over-statement, but it is likely that twelve thousand tons is more accurate.

In the early days of the industry the principal seaweeds used by the kelp burners were the bladder-racks (*Ascophyllum* and *Fucus* species) because they contained the highest proportion of soda. The manufacturers sought it as a less expensive substitute for material called barilla soda which had to be imported from Spain. There came a time, though, when the duty on barilla was reduced and then soon afterwards the mineral deposits of Stassfurt were discovered. Both these events, as might be expected, most loudly sounded the death-knell for kelp, but the price was at hand. This came in the discovery of iodine, and in the further discovery that the seaweeds (species of *Laminaria*) were rich in this new element. The first factories for the extraction of iodine were built in France soon after 1820, and by 1843 the trade was once more flourishing. This stimulus given to the kelp trade by the discovery of iodine did not persist for long, because in 1873 the discovery of the oil resources dealt the industry a blow from which it never recovered.

Both in France and the Orkneys there was opposition at the start to kelp-burning because it was thought that the fisheries would be damaged. In the Orkneys a number of trials even took place. Later, however, when the industry formed a livelihood for forty thousand people, the old Highland toast 'a high price to kelp and cattle' was witness of the change of mind.

When bladder-wrack was the principal source of kelp the right to cut it was a jealously guarded privilege retained by those whose land adjoined the beach, and in France a number of decrees laid down

the regulations. Thus we find that the rockweeds or *goémon de rive* are described as those which are attached to the ground and may be reached dry-shod at low water of spring tides, but we go on to learn that the regulation dry-shod means that the cutter can enter the sea *jusqu'à la ceinture*!

In France the oarweeds were cut by special workers known as *soudeurs* or *goémonniers* who had to obtain a licence, but in other countries there were often no restrictions and the submarine forests of the sea were open to all who cared to carry out the arduous work. A satisfactory method of harvesting these growing weeds is indeed one of the main problems still confronting present-day operators in Europe. Cast weed, however, seemed to come into a different category. It was evidently considered that this was more or less common property, and in order to ensure that no quarrels should arise from its collection, each town, hamlet or region drew up its own rules. Thus in the Orkneys when a 'brook of ware' was thrown ashore the laird's factor divided the cast into a number of lots, and each crofter took so many lots according either to his acreage or his rent. The actual site of the lots was settled by ballot. In France much the same practice was followed. In the Isle d'Ouessant, after a gale had blown a good cast ashore, it was the privilege of the oldest inhabitant to mark it out into equal portions. When this was completed each family was permitted to take away as many lots as there were members in the family, but were only allowed to collect them "when the lighthouses were extinguished".

The old method of burning the dry seaweed in open kilns was wasteful as much of the iodine was lost to the atmosphere. Indeed, Cauer¹ has maintained that the high iodine *maheu* of central Europe is directly attributable to this fact. This loss and the impossibility of drying seaweed in the winter led to a search for an improved extraction process. The chemist E. C. Stanford was most active, and he first proposed the char or distillation process². Stanford naturally met considerable and determined opposition to his new method from the conservative kelpers. In a great effort to try to convince them that his technique was superior, he arranged that one of the most experienced crofters should pit himself in a test against him (Stanford), and there was no doubt that Stanford produced the better product. But the Hebridean crofters are not thus to be readily daunted, and so the old kelper turned to him and said, "I have been making kelp for fifty years and more, and am I to be taught by a young Sassenach with no beard on his face to speak of!"

Later Stanford invented the lixiviation process, which is of considerable importance because by this technique he obtained alginate acid. This substance, discovered by Stanford, is likely to prove the most important product to be obtained from the brown algae³. A number of factories were built but the laboratory processes just described could not be made to work satisfactorily on a commercial scale and much money was lost, this contributed to the collapse of the industry as a whole. It is, one hopes, partly to avoid a repetition of this error that the Scottish Seaweed Research Association has been formed.

Variants of both the char and lixiviation processes have been evolved but none of these appears to have been more successful than the originals. A Russian technique is, however, of more than passing interest. The Russians are not employing the oarweeds but instead a red seaweed, *Phyllophora nervosa*, which grows

abundantly in the Black Sea and is very rich in iodine. Water containing the chopped alga is electrolysed at increasing potentials, iodine separating out at the lowest, then bromine and finally chlorine at the highest. The solution is then concentrated and further electrolysis yields mannite and alginates.

In the past mistakes have also been made by scientific workers in not paying sufficient attention to (a) season of the year, (b) type of locality, (c) age of material, (d) proportion of stipe to lamina in the sample. Here again the S.S.R.A. will, it is hoped, see that these gaps are adequately filled. If the kelp industry in a new form can be started again it should go far to improve the lot of the crofters in the Highlands and Isles of Scotland if their natural prejudices can be overcome. The poverty of these people has to be seen to be believed—the habitations compare unfavourably with many of our slums, and overcrowding in small, ill-lit and badly ventilated cottages with their heavy peat smoke atmosphere is the rule rather than the exception. Any effort, therefore, that will improve their lot is to be welcomed.

GENETICS IN RELATION TO DISEASES OF ANIMALS AND PLANTS

AT a joint meeting of the Association of Applied Biologists and the Genetical Society, held in London on March 23, the problem of the "Genetic Relations of Plants and Animals to their Pests and Diseases" was discussed.

Dr C. D. Darlington (president of the Genetical Society) opened the proceedings by emphasizing the two fundamental facts that all species of animals and plants vary genetically in their power of resistance to, or defence against, disease, and that all disease organisms vary genetically in their power and mode of attack, and in their resistance to our control methods. Variability is the rule rather than the exception or nature, but crop and stock improvement in the last fifty years had tended to reduce variability within the different cultivated races even to the extent of producing, at times, a homozygous pure line. One of the problems of the future must be to introduce new variation into the cultivated forms. He also discussed the power of plants to produce antibodies to a virus, and considered that the recent work of J. M. Wallace (*J. Agric. Res.*, 69, 187) showed that antibodies to a virus are produced by tobacco and that they can propagate themselves in the tomato plant, which cannot itself develop them.

Dr J. Hammond dealt with constitution in cattle in relation to pests and diseases, particularly as illustrated by the introduction of European cattle into the tropics. There they are particularly susceptible to local pests and diseases to which the native or other tropical cattle are comparatively resistant. European cattle have a higher level of tick infestation than the zebu, possibly due to their longer hair and higher body temperatures. There is no evidence of any immunity to tick fever in the zebu, but the resistance to its effects is much higher than in European races, and first crosses come much nearer to the zebu. Body temperature and respiration-rate

have been measured in crosses and back-crosses between zebu and European cattle under tropical conditions. Milk production and growth run parallel with their resistance to tick fever, and there is little doubt that they are all dependent on differences in physiological constitution connected with heat regulation at high air temperatures. New tropical breeds—for example, the Santa Gertrudis and the Philamin—are being formed to combine the productive power of European beef cattle with the heat-, tick- and disease-resisting qualities of the zebu.

Michael Pease discussed the inheritance of disease resistance in poultry. He said that it had been claimed that the virtual disappearance of fowl paralysis in recent years had been due to selective breeding. In the Cambridge flock the disease was first noticed in 1930, increased to an alarming peak in 1935, and thereafter declined to negligible proportions in the war years. This was typical also of other parts of the country. In spite of this, analysis of the breeding results year by year gave no evidence that inheritance played any part in the incidence of the disease. With regard to non-specific disease in poultry it was widely held that this was due to breeding from too young birds. A statistical analysis of chick and adult mortality at Cambridge had shown that the determining factor was not the age of the mother, but whether she died during the breeding season or survived. Mothers which died early during the season left progeny with an excessive death-rate. The age of death of the cock was without any apparent effect.

Dr J. S. Carr discussed the heritable susceptibility to cancer in the domestic fowl. The incidence is high in all breeds throughout the world, and it is generally considered that the majority of cases are due to the action of carcinogenic viruses, of which number are known. Using Rous No. 1 Serum as test virus and 6-8-week old chicks as host, it was possible to show that the main factor determining known growth was the genetic constitution of the host. From a flock of Brown leghorns it was found possible to build up by selection a line with very high resistance to this virus. The line was also resistant to other carcinogenic viruses and to a certain extent to chemically induced tumours.

Dr William Black discussed the inheritance of resistance to blight (*Phytophthora infestans*) in the potato. A wild polyploid (*Solanum demissum*) was used as the source of resistant genes. Three strains of blight, A, B and C, were isolated and four resistant phenotypes were differentiated as follows:

- | | | |
|-----|--------------------|----------------------------|
| (1) | Plants immune from | A, B and C |
| (2) | " | " " A and B but not from C |
| (3) | " | " " A and C but not from B |
| (4) | " | " " A but not from B and C |

As all these were immune from A it appears that this strain is less virulent than the others, but the difference in virulence between B and C appeared to be qualitative rather than quantitative. A series of parallel tests of derivatives of three species, *Solanum tuberosum*, *S. demissum* and *S. tuberosa*, led to the conclusion that immunity from A and B is controlled by two major genes, *Ra* and *Rb*. Plants carrying *Ra* are immune from the A strain, while plants carrying *Rb* are immune from both A and B.

Dr G. Cockerham discussed the genetical aspects of resistance to potato virus and particularly the problem of 'hyper-sensitiveness' which causes such rapid death of the tissues round the point of infection that the virus is unable to spread. This results in what is

lles 'field immunity' A single dominant gene N_x induces hyper-sensitiveness to several strains of virus X but not to other aberrant strains Another gene N_a determines hyper-sensitiveness to virus A, and in each of six cultivated varieties this is closely linked with N_x In the variety South-Esk, however, the two genes are independent Still another gene N_c determines hypersensitiveness to virus C which is a strain of virus Y No cultivated variety of potato hypersensitive to virus Y, but five clones of three ferent 'wild' species showed characteristic responses when infected in the laboratory Dr Cockerm believes that 'hyper-sensitiveness' is a character of significant value in virus control

Prof T J Jenkin gave a short account of work in connexion with disease and pest resistance at the Welsh Plant Breeding Station at Aberystwyth, which is concerned chiefly with the production of new varieties of oats, clover and herbage grasses By selection from mixed population a variety of oat, 75, has been produced which is highly resistant to rust (*Ustilago*), and the white winter oat variety, 81, is one of the most resistant to eelworm In clover, special attention has been paid to finding strains resistant to clover rot (*Sclerotinia trifoliorum*) and eelworm (*Tylenchus devastatrix*) Here the choice of breeding material is far wider than in oats owing to the heterogeneity of the crop and the heterozygosity of individual plants

In the discussion which followed the principal speakers, Prof W J B Riddell directed attention to the effect of the different varieties of *Pneumococcus* causing pneumonia In Glasgow, type II occurred with higher frequency than in Manchester, where type I was the most common Since the introduction of chemotherapy, type II had relatively increased in Glasgow.

Dr K. Mather mentioned the work of Lindstrom and his pupils on the bacterial wilt of maize In this disease the bacterium increases in virulence by passage through a resistant inbred line of maize, but decreases virulence by passage through a susceptible line In mixed inoculations the virulent strain is selectively favoured by resistant maize and the avirulent by susceptible lines.

Mr A. Crane discussed the effect of the use of 'monoclonal' crops and suggested that some of the dangers might be avoided by the regular production of short-lived clones or by the regular production of F_1 hybrids which are sufficiently uniform for commercial requirements Virus infection upsets uniformity even in clonal crops In some vegetatively produced plants the position has now been reached when as much care, or more, has to be given to the nursing of old clones as to their cultivation

F C Bawden did not agree that present available evidence proved the existence of virus antibodies in plants.

Dr H. W Howard said that at Cambridge experiments had been carried out to obtain potatoes resistant to blight, using *S. demissum* as the source of immunity, with results very similar to those obtained by Dr Mack at Edinburgh In F_2 and F_3 , however, there was some indication of the effect of modifying genes of importance He considered that the genetics of the parasite (*P. infestans*) needed more investigation Strains from single spores had not changed their virulence and the origin of new strains may be due to sexual reproduction.

R. Stenton suggested that the ratio of diseased individuals in a mixed population of unknown genetic

constitution might be found to be proportional to the number of recessives present.

Dr C B Williams (president of the Association of Applied Biologists), in summing up, re-emphasized the importance of keeping a high level of variability in the host plants or animals as a protection against possible new diseases in the future He gave a short account of work recently carried out by Dr S C Harland in Peru on the selection of cotton Harland started with a very large number of plants tested individually for a small number of commercially valuable characters, and selected for these only, leaving all other characters as variable as possible He avoids all self-fertilization which produces a large proportion of homozygotes in all characters both visible and invisible.

C B. WILLIAMS

ARCHAEOLOGICAL EXPLORATION IN SOUTH AFRICA

SEVERAL interesting articles on archaeological topics have been published recently in South Africa Prof van Riet Lowe and Prof. H Breuil have been studying a number of Stone Age sites in southern Mozambique, not so far from Lourenço Marques^{1,2} It is true that both reports are very much of an interim nature, and that, except for a page of pottery profiles in one of them, they are unillustrated, but they are important, for enough has been found to show that, archaeologically speaking, the area is going to prove of very significant interest. Early palaeolithic finds, including some of a Clacton-Abbevillian facies, occur along the foot-hills of the main mountain chain and in the river valleys At the time when their makers were alive, it seems that the sea coast lay farther inland than it does to-day. Later Stone Age industries occur nearer the present shore-line

Mr B D Malan, of the Archaeological Survey, has issued a handy little instruction pamphlet for the use of would-be excavators³ Of course, a pennyworth of practice *under supervision* is worth pounds of theory, but there is room for the latter, too It is perhaps a pity that no 'tips' for studying rock-shelter paintings and rock carvings are given

Prof. van Riet Lowe's notes on the laws in South Africa governing archaeological and vertebrate palaeontological research⁴ will be read with mixed feelings On one hand, certain classes of sites are limited in number, and once spoiled by well-meaning but untrained amateur investigators their evidence is for ever lost On the other hand, it is not too much to say that most of our archaeological knowledge to-day has been due to the devoted efforts of amateurs in the past Many an amateur excavator is as good, if not better, than his professional confrère To have a paid job as a prehistorian, whether in a Government department or at a university or in a museum, does not thereby endow the holder with the attributes necessary for a really good observer in the field If regulations are made too tight, the amateur's interest in the subject tends to flag and his intellectual energy to be transferred to other fields As a result the subject ceases to attract the general public, and a 'hobby subject' needs public interest if it is to continue to progress In South Africa, the law permits surface finds to be freely collected, but certain types of sites (sealed deposits) are taboo, and so is the "removal and export of vertebrate fossils", and many

official forms have to be filled in before they can be touched by the would-be investigator. Maybe this is a right move, if it can be enforced. Otherwise sites will be stripped by collectors and no records kept. Then indeed the evidence will be totally lost to science.

These problems equally apply to Great Britain. We must face the risk of total loss of valuable evidence due to ignorant amateurs, or the stifling of nearly all amateur effort by bureaucratic control. These are the twin horns of the dilemma. Probably the best solution lies in the education of the local archaeological societies and the growth of a public opinion which would ensure that the local society is approached for expert help before any amateur attempts are made to tackle a serious excavation. But even this is not quite so simple as it sounds.

FORTHCOMING EVENTS

Tuesday, June 5

ROYAL ANTHROPOLOGICAL INSTITUTE (21 Bedford Square, London, W C1), at 1.30 p.m.—Prof A R Radcliffe-Brown "African Gods and Christian Saints in Brazil" (postponed from May 8)

Wednesday, June 6

SOCIETY OF CHEMICAL INDUSTRY (NUTRITIONAL PANEL) (at Chemical Society, Burlington House, Piccadilly, London, W 1), at 2.30 p.m.—Dr D P Cuthbertson "Protein Hydrolysates: their Preparation and Clinical Uses"

ROYAL ENTOMOLOGICAL SOCIETY (41 Queen's Gate, London, S W 7), at 3.30 p.m.—Dr A G Hamilton "Further Studies on the Relation of Humidity and Temperature to the Development of African Locusts"

Thursday, June 7

THE LINNEAN SOCIETY (joint meeting with the ZOOLOGICAL SOCIETY) (at the Linnean Society, Burlington House, Piccadilly, London, W 1), at 4.30 p.m.—Dr C Leighton Hare "Some Features of the Structure and Life-history of *Evocaulon septangulare* With and their Bearing on its Geographical Distribution", Dr A Tindell Hopwood "Contributions to the Study of some African Mammals (3) Adaptations in the Skeleton of the Fore-limb of Lion, Leopard and Cheetah"

Friday, June 8

ROYAL ASTRONOMICAL SOCIETY (Burlington House, Piccadilly, London, W 1), at 4.30 p.m.—Discussion on "Extra-Galactic Nebulae", among the speakers will be Dr A Hunter, on "The Observational Details of the Resolution of Extra-galactic Nebulae into Stars", and Mr J H Reynolds, on "The Apparent Distribution of the Extra-Galactic Systems and the Validity of the Magnitude-Scale"

ROYAL INSTITUTION (at 21 Albemarle Street, London, W 1), at 5 p.m.—Lord Moran of Manton "Courage and Fear"

PHYSICAL SOCIETY (at the Physics Department, Imperial College, London, S W 7), at 5 p.m.—Demonstrations

Saturday, June 9

BIOCHEMICAL SOCIETY (at the Institute of Physiology, University of Glasgow), at 11.30 a.m.—Scientific papers

INSTITUTE OF PHYSICS (ELECTRONICS GROUP) (in the Fyvie Hall, The Polytechnic, 309 Regent Street, London, W 1), at 2.30 p.m.—Discussion on "Some Aspects of High Vacuum Technique" ("Glass-to-Metal Seal Design", introduced by Mr W J Scott, and "High Vacuum Pumps", introduced by Dr R Witty)

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned

LECTURER IN THE DEPARTMENT OF PHYSIOLOGY AND BIOCHEMISTRY, King's College, Strand, London, W C 2—The Secretary (June 8)

LECTURER IN APPLIED MATHEMATICS at King's College, Newcastle-upon-Tyne—The Registrar (June 9)

ASSISTANT LECTURER IN PHYSICAL AND INORGANIC CHEMISTRY Queen Mary College (University of London)—The Acting Registrar Queen Mary College, c/o King's College, Cambridge (June 10)

AGRICULTURAL TRAINING OFFICER to organize training in agriculture of persons released from war service—The Executive Office Holland War Agricultural Executive Committee, 15 Market Place, Boston, Lincs (June 16)

LECTURER IN ELECTRIC ENGINEERING at Kendrick Technical College, West Bromwich—The Director of Education, Educational Offices, Highfields, West Bromwich (June 16)

SUB-LIBRARIAN at Bedford College (University of London), Regent Park, N W 1—The Secretary (June 20)

LECTURER IN CHARGE OF THE DEPARTMENT OF BOTANY at University College, Leicester—The Registrar (June 20)

LECTURER IN MECHANICAL ENGINEERING at Brighton Technical College—The Education Officer, 54 Old Steine, Brighton, 1 (June 2)

PRINCIPAL of Nottingham and District Technical College—Acting Clerk to the Governors, Education Office, South Parade, Nottingham (June 30)

LINACRE PROFESSOR OF ZOOLOGY AND COMPARATIVE ANATOMY University of Oxford—The Registrar, University Registry, Oxford (July 7)

SECRETARY OF THE ROYAL GEOGRAPHICAL SOCIETY—The Honorary Secretary (July 31)

PROFESSOR OF AGRICULTURE and also a READER IN PHARMACY in the University of Sydney—The Registrar (six copies of application stating age, experience, publications, medical certificate and recent photograph are required) (August 18)

LECTURER IN SOCIAL ANTHROPOLOGY in the University of Edinburgh—The Secretary (September 30)

PROFESSOR OF BOTANY, a PROFESSOR OF ECONOMICS, and a SENIOR LECTURER IN ZOOLOGY, at Auckland University College (University of New Zealand)—The Secretary, Universities Bureau of the British Empire, c/o University College, Gower Street, London, W C 1

PHARMACIST for the Northern Rhodesia Government Health Department—The Secretary, Overseas Manpower Committee (Ref 125 Ministry of Labour and National Service, York House, Kingsway, London, W C 2)

BOTANIST for the Intelligence Section of the Plant and Animal Products Department of the Imperial Institute, London, S W 7—The Establishment Officer

LECTURER IN BIOLOGY (woman) at Edge Hill Training College Ormskirk (now at Bingley, Yorks)—The Principal

MAN IN THE MODERN WORLD

MR MUMFORD'S aim in the series of volumes that opened with "Technics and Civilization" was to give a rounded interpretation of the development of modern man, and to show what changes in his plan of life are necessary in order to enable him to make the most of the vast powers that are now at his command. The third volume, which has now appeared*, deals with the purposes and ends of human development. Whereas in his former volumes Mr Mumford was concerned with the effect of technical and social factors on the condition of man, he is here concerned with that of symbols, or what he terms the 'idolum' which complements man's natural environment. By this term he understands a symbolic milieu of images, sounds, words, fabrications, and even natural objects to which man has attached a representative value. The ability to write symbols and respond to symbols, he says, is an essential difference between the world of brutes and the world of men. Communication, communion and co-operation, the three essential attributes of human society, all depend upon the acceptance of common symbols to which the same meanings, functions, and values are attached. They are not substitutes for experience but a means of enhancing it and enlarging its domain, and ritual, art, poetry, drama, music, dance, philosophy, science, myth and religion are all as essential to man as his daily bread. It is through the effort to achieve meaning, form and value that the potentialities of man are realized, and his life raised to a higher potential, and this survey of the condition of man attempts accordingly to emphasize those aspects of man's life that are usually neglected—his dreams, his purposes, his ideals, his utopias.

From this point of view, Mr Mumford sets out to survey in its social setting the whole history of the mind of man from ancient Greece to Nazi Germany, to describe the conditions of life, material and spiritual, in which thinkers and philosophers arose, to characterize and evaluate their teachings, and, finally, to find a fresh answer to the age-long questions: What is man? What meaning has his life? What is his origin, his condition, his destiny? Mr Mumford seeks to determine whether any regular trends are to be found in human history and whether these throw any light on future possibilities. But while he attempts no study of ethical ideals, of the purposes which men ought to pursue, he makes many excursions into philosophy, and enters judgments in that field which are at least provocative and may be irritating, though it is argument and not contradiction that in the main he will stimulate.

The task Mr Mumford has set himself is immense and may seem unmanageable, but a strong sense of historical continuity informs his attempt at synthesis. Sometimes this leads him to oversimplify the issues, to concentrate on the history of ideas and to neglect the task of delineating the conditions in which men actually lived. "The Culture of Cities" may indeed correct the impression of unity and coherence in

* The Condition of Man. By Lewis Mumford. Pp x+467+16 plates (London: Martin Secker and Warburg, Ltd, n.d.) 25s net

some of his descriptions in the present book, for Mr Mumford is here apt to concern himself too much with the spiritual side of the history of Western man, and his dramatic bias, as indicated in his chapter titles, tends to accentuate the weakness. He gives too much of the impression of a closed chapter to each epoch, rather than of continuous development. Nevertheless, the fundamental theme of the book is that man is a continually changing animal, his growth is not completed by biological fulfilment as mate and parent or by death, his nature is self-surpassing and self-transcending, his utmost achievements are always beginnings and his fullest growth leaves him still unsatisfied, while above his instinctive and automatic activities lies a whole stratum of purpose and meaning. Mr Mumford has attempted, not to trace lines of development, but rather to discover in each period of human history the forces which tend to encourage or thwart the realization of personality. In dealing with each age he weaves into a single pattern all that is known of its religion and art, as well as of its social and political organization. He often challenges accepted beliefs and opinions, but even when he fails to substantiate his own views sufficiently, he demonstrates the resources of the reservoir of human creativeness to be found in history.

So far as scientific workers are concerned, they may feel that the contribution of science is insufficiently stressed by Mr Mumford, and may be tempted to compare his book to its disadvantage with Whitehead's "Adventures of Ideas". But while Mr Mumford has been over-careful to avoid repeating the argument of "Technics and Civilization", he does justice to Bacon and Newton, and one of the most suggestive passages of the book is that in which he discusses the relation between science and the universities at that time, and the way in which science came to acquire a moral authority that had once been pre-empted by the Church.

When dealing with science and its implications, Mr Mumford is in fact at his best. In the last three chapters of his book, which are much the best written and most lucid, if not indeed also the most stimulating, he passes in review the nineteenth century and seeks to disclose the roots of the dangers threatening Western civilization and to formulate a basis for renewal. Here is indeed a sombre picture of societies dominated by intensified nationalism, of the triumph of the machine over human personality and of moral weakness rationalized with the help of theories in which brute impulse is given priority over reason.

A formidable mass of reading, not all of equal value, is represented by the bibliographies appended to his books, but it is in the writings of a man of science, Patrick Geddes, that Mr. Mumford finds the clue to the basis of renewal. Geddes' emphasis on the evolution of a more finely attuned and more complexly balanced expression of both personality and community, and his philosophy of life in which mechanism had constant place as the servant of life but never as its master, led him to an expression of citizenship akin to that which Mumford has already indicated in "The Culture of Cities". Geddes accepted social

responsibility in his life and work, and interrelated scientific investigation with social need, but the change he advocated was the unification of all the processes of life, the subjective and the objective, and the equal cultivation of the sciences, the arts, and the humanities.

Mumford's tribute to the work and teaching of Geddes is deserved, but while Geddes expressed Mumford's own view that the sundered fragments of the modern world will be unified, not by returning to their original simplicity but by advancing to a more highly developed synthesis and a more inclusive pattern of action, open always to the test of fresh action, to the challenge of fresh experience, and to inclusion of fresh ideas and ideals, Mumford's final chapter has much in common with General Smuts' conception of holism. None the less, this final chapter is not exhaustive in its analysis and rather deficient in the delineation of the ways in which the needs of personality and those of the community are to be fulfilled in due balance, is perhaps the most stimulating in the whole book. It is full of pertinent comments as we face the tasks of a post-war world, and is less sombre than most of the book, for Mr Mumford faces the future with hope. We are moving, he thinks, from an age of expansion to an era of stabilization, which will present an opportunity for a proper balancing of functions, and therefore for a richer development of personality. To make greater use of our vitalities and energies we must re-assert the primacy of the personal.

Mr Mumford points out that every gain in power, every mastery of natural forces, every scientific addition to knowledge has proved potentially dangerous because it has not been accompanied by equal gains in self-understanding and self-discipline. If he seems to be paraphrasing Smuts' own words to the British Association, but the last ten years abundantly attest the truth of his further observation that science which disclaims all interest in human values except the satisfaction of curiosity and the increase of manipulative skill, cannot be useful even in its limited sphere when the general dissolution of values leads to a contempt for science and a deliberate perversion of its values. The watchwords of the new culture must be cultivation, humanization, co-operation and symbiosis. Many of our present mistakes are due to statesmen, industrial leaders and administrators attempting to apply the ideology of the age of expansion to a social organization with entirely different requirements—an organization in which careful timing and spacing of activities, the provision of diversified opportunities and the balancing and interlocking of functions must take the place of spectacular one-sided advances.

While the conditions for stabilization have not yet appeared, the institutions that will turn this process to the advancement of society have not yet been developed. For working out the new social order we need active knowledge of the social environment, and the behaviour of men in social partnerships, their needs, their drives, their impulses, their dreams as indispensable as reading, writing and arithmetic to those trained to capitalize. The art of politics and the arts of enlightened behaviour and orderly commun-

ions must become the main field of new inventions, and here Mr Mumford enters a plea for a world language

The great gains made in technique during the last few centuries have been largely offset by a philosophy that either denied the validity of man's higher needs, or sought to foster only that limited set of interests which enlarged the power of science and gave scope to a power personality. Hence Mr Mumford puts first among our tasks of post-war reconstruction, not the physical re-building, but the laying in every department of our culture of the foundations for a new set of purposes, a radically different mode of life. "Civilizations," he observes, "do not die of old age—they die of the complications of old age," and the task for our age is to decentralize power in all its manifestations. Our first need is not for organization nor for the mobilization of organization that has become inflexible—but for re-orientation, a change in reaction and attitude. There are new organizations, large and small, set up under stress of war, on which we can draw, but we must bring to each activity and every plan a new criterion of judgment: how far it tends to further the process of life-fulfilment, and how much respect it pays to the needs of the whole personality.

There is no easy formula for this renewal, and the real needs further analysis. The question whether the age of expansion is ended should be explored more deeply if by expansion we mean increasing control over the forces of Nature, including human nature. But if Mr Mumford is sometimes incomplete it is always suggestive, and his book is one to be pondered by all concerned with the trend of civilization. As already indicated, it is not free from faults. Historically, Mr Mumford tends to defeat his own object by dramatizing episodes in a way that masks a continuous development of human culture, and a strong Socinian bias mars his presentation of Christianity. But as a social philosopher he has the confidence and forward-looking mentality of the Mannheim school, and the whole weight of the book thrown in support of an adequate programme of social research in the true sense of the word. He comes also in support of the planning school, but he is not balanced to be led into excess, and his emphasis is freedom to be achieved only when the new ordering of our environment has permitted the development of personalities capable of drawing upon immense stores of energy, knowledge and wealth without being demoralized by them. Above all at the present moment it is for its note of hope, the confidence with which, surveying the disintegration of civilization, he summons us to the task of re-integration, that Mr Mumford's work is most welcome and should be studied, particularly by scientific workers, whose contribution to the task he recognizes as only as he stresses its limitations. This is the voice of a prophet and interpreter, calling us to seek the truth rather than declaring it plainly, and, though the message is not new, the world picture is clearer, more coherent and more relevant to post-war tasks. In that General Smuts drew for the centenary of the British Association

PRIMITIVE PERSONALITIES

The People of Alor

A Social-Psychological Study of an East Indian Island. By Cora Du Bois, with Analyses by Abram Kardiner and Emil Oberholzer. Pp xi+654+32 plates (Minneapolis, Minn.: University of Minnesota Press, London: Oxford University Press, 1944.) 45s 6d net.

DR DU BOIS received her training in anthropology at the University of California. Her subsequent field-work among American Indians on the west coast of America led her to realize the dangers of supposing that we can deduce what individuals are from the institutions under which they live. "psychological orientations and techniques" need to be employed for this purpose, and analytic psychology appeared to her "to offer the greatest number of concepts with which the anthropologist could operate, although much of its theory, particularly in the field of social phenomena, seemed inept." Thus it came about that in 1935 she spent a year as a U.S. National Research fellow, in exploring "the bearing of various psychiatric approaches to personality formation within our own society", and that in the spring of 1936 and 1937 she collaborated with Dr Abram Kardiner in his seminar at the New York Psychoanalytic Society. Together, they reached the conclusion that field-work alone could test the validity of the procedures which these seminar discussions had indicated. Aided by funds contributed by Dr Kardiner, the Social Science Research Council of Columbia University gave Dr Du Bois the financial support which enabled her to carry out such field-work.

Dr Du Bois's choice fell on Alor, a remote island north of Timor, fifty miles long and thirty miles broad, in the (then) Dutch East Indies. There she arrived in 1938 and at once built herself a house, among some six hundred mountain people, in a district called, from the name of its largest village, Atimelang, and comprising four other villages. The Atimelangers, Dr Du Bois tells us, are predominantly Oceanic Negroids, with Oceanic Mongoloid admixture and with perhaps a strain of pygmy origin. About ten thousand of the coastal people of Alor are Mahomedans, the rest are pagan. In Atimelang she stayed for eighteen months, returning to New York in the winter of 1939-40.

This book, the principal fruit of her expedition, is divided into four parts. The first is introductory. The nine chapters of the second part, styled "psycho-cultural synthesis" (in which thirty-one pages of excellent photographs are inserted), deal with infancy, childhood, adolescence, marriage, sex, adults and institutions, some psychological aspects of religion and some personality determinants in Alor culture. The third part, by far the longest, comprises more than 360 pages and contains the autobiographies of eight Alorians, four men and four women who, the author believes, "represent, on the whole, average Atimelang adults". These autobiographies were recorded with the help of a native interpreter, about fifteen interviews, of an hour each, were accorded to each of these eight informants. The fourth part of the book describes the results of the four psychological tests she applied—the Porteus Maze tests (scored and briefly commented on by Dr Porteus himself), word associations, children's drawings and the Rorschach test (evaluated by Dr Emil

Oberholzer, an enthusiastic expert on this test) They were applied respectively to 55, 36, 52 and 37 Alorese, and must be regarded as tentative, exploratory efforts

To Dr Du Bois's presentation of 'the problem' in her first chapter Dr. Kardner adds an 'elaboration' (as she terms it) of somewhat greater length To the second part he also contributes its last chapter, and to each of the eight autobiographies he appends an analysis of the personality and a diagram of the 'character structure' of each informant, adding a final chapter in which he surveys the biographies as a whole and compares them individually The contributors of these biographies received payment for each of their attendances "It was understood," Dr Du Bois states, "that each session would begin with dreams of the preceding night," and sometimes she had doubts as to the genuineness of these dreams Sometimes, too, the interference, and indeed the very presence, of the interpreter acted as an obstacle to securing the complete confidence and truthfulness of the informant. Nevertheless, these autobiographies reveal striking individual differences in personality, and they contain an abundance of ethnographic material which would probably have been unobtainable by any other, less novel, method, and when Dr Du Bois felt compelled to intervene in the narratives, these occasions are meticulously indicated in the text Few psychoanalysts, if any, will quarrel with Dr Kardner's interpretations of this material care and caution characterize his analyses But such phrases as "the tonicity of the super-ego", "inflation of the parental imago" and "weak libidinal ties" must prove deterrent to those who, like the reviewer, are less familiar with Freudian terminology than he is His reasonable concept of 'basic personality' (or 'modal personality', as Dr Du Bois prefers to term it) recurs throughout the book It implies "the psychic unity of mankind"—arising from "the interplay of fundamental physiologically and neurologically determined tendencies and experiences common to all human beings being acted upon by the cultural milieu, which denies, directs, and gratifies these needs very differently in different societies" As Dr Kardner observes, "no two individuals subjected to exactly the same cultural influences will utilize them in exactly the same manner" But in each society there is a 'central', or 'modal', tendency

When, on her return to America, Dr Du Bois presented her material for discussion at the Columbia University seminar, Dr Kardner, we are told, employed a certain technique and reached certain conclusions But, he says, Dr Oberholzer, to whom the Rorschach test material was submitted, "was acquainted neither with the technique that I pursued nor with its conclusions, nor did I know what the conclusions of the Rorschach tests were likely to be When these conclusions were finally presented, the correspondence between characteristics common to all Alorese and the reconstruction of the 'basic personality structure' was truly remarkable Furthermore, the differences between Alorese and Western man demonstrated by the Rorschach tests were equally striking" The reviewer, however, is not impressed by the closeness of correspondence between Dr Kardner's and Dr Oberholzer's descriptions of the personalities of individual Alorese whom they each analysed

"It is not the purpose of the present account," Dr Du Bois explains, "to give a thorough ethnographic

description" of the Alorese This is obvious, and such details, which "must await separate publication", will receive a hearty welcome Her present work is a serious attempt to effect collaboration between modern anthropology and so-called 'depth psychology', in the field of social studies It is, a Dr Ruth Benedict observes, "a pioneering contribution to the study of personality in an alien culture"

THE SCHOOL CURRICULUM

The Content of Education

By J A Lauwerys Pp 24 (London Association for Education in Citizenship, 1944) 4d net

Science in Childhood Education

By G. S Craig Pp 86 (New York Bureau of Publications, Teachers' College, Columbia University, 1944)

READERS of the *Spectator* will recall a recent article bearing the challenging title "Teaching the Wrong Things", and they will probably agree that the writer of the article made out a good case to say the least, for a revision of our notions of what should be taught in our schools The call for revision does not come directly from the teaching profession itself, partly because teachers are too much occupied with the social side of their work to think about departures from the traditional curriculum, and partly because their noses are kept to the grindstone by the requirements of external examination

That the problem is in the air, however, and that it is receiving attention by people who take an active part in schemes of thinking and planning for the future, is well exemplified by Mr Lauwerys' pamphlet "The Content of Education" The writer is well aware of the difficulties of the job he has so courageously tackled There are some who say that it does not matter what you teach so long as the children are kept busy and happy, others who say that it does not matter so long as children are put through the mill of strict mental discipline, and still others who seem to agree with the famous headmaster quoted by Mr Lauwerys, that it did not matter much what was taught in his school, provided the boys loathed learning it In his well-packed pamphlet Mr Lauwerys first reviews the actual content of existing curriculum and then proceeds to ask how it has all come about Then follows an exposure of failure of the curriculum to meet the needs of children, as those needs are seen from the sociological point of view Finally, definite proposals for reform are summarized, following the lines laid down by the Association for Education in Citizenship

Mr Lauwerys refrains from dealing radically with the usual list of 'subjects'—a word which has much mischief to answer for, but which cannot be dispensed with The most significant of the reforms suggested comes under the head of social studies "For a long time progressive teachers of history and geography have tried working at combined courses in their two subjects Some feel that this proposal needs extending" They desire that there should be courses in social studies consisting of "material taken from history, geography, politics, economics, anthropology, social psychology" Such courses are being successfully given both in Britain and in the United States They deal with problems studied under such headings in such a way that when the treatise

s taken to a higher level they "tend to crystallise out into these subject-divisions"

The work entitled "Science in Childhood Education", by the professor of natural sciences in Teachers' College, Columbia University, shows that dissatisfaction with the present 'content of education' exists in the United States no less than in Britain. The question discussed in this work is the position of science in the education of children. Though, says the editor of the series to which this book belongs, science in some form has a widespread influence on our day-by-day living and thinking, yet it has made very little headway in schools for children of less than fourteen years of age. The lag seems to be due to the inclination to look at science only in terms of 'specialised fields', that is, of the 'subjects' which trouble Mr Lauwerys. One cannot teach "physics, chemistry, biology and the others" to children, and no satisfactory scheme has been devised to meet the needs of children who are assailed on every hand by the marvels wrought by modern science.

Prof. Craig's work has been inspired, not by a desire to defend science as a vested interest, but by a concern for aiding children to use scientific procedures and information as a means of dealing with problems they encounter and of understanding their environment. He has performed his task with admirable thoroughness, but the teachers of American children must not expect to find the book easy reading. It is, however, an interesting confirmation of our own concern for meeting the real needs of twentieth-century children.

ELECTRICAL TRANSMISSION FREQUENCIES

High Frequency Transmission Lines

by Dr Willis Jackson (Methuen's Monographs on Physical Subjects) Pp vii+152 (London: Methuen and Co., Ltd., 1945) 6s net

DURING the early stages of the industrial applications of electricity, direct current held sway in both telecommunication and power transmission. Under the influence of Kelvin and Edison, direct current continued to be used for the latter purpose, long after the practical superiority of alternating current had been fully demonstrated. At present, all the most important power transmission is done at frequencies of 50-60 cycles per second. There are, however, great difficulties in the way of extending alternating current power transmission over distances exceeding say 400 miles, and much thought is being given to reversion to D.C. for projects such as the transmission of powers of the order of a million kW. The wheel has therefore turned almost all circle.

In telecommunication, the trend has been from the D.C. or zero frequency telegraphic systems towards radio frequencies of the order of 10^9 cycles/second. High-frequency transmission lines have been used extensively for telecommunication purposes during the last five years, and have improved the efficacy of channels to a remarkable extent. This improvement has involved revolutionary changes in sending and receiving apparatus, and in the form and constitution of the interconnecting cables. Short-wave radio-type equipment does the transmitting and receiving over or through special channels, the best known of which is the coaxial cable. The cable must be constructed

in such a way that there are no abrupt changes in its capacity or inductance per unit length, and the dielectric losses in the insulation must be as low as possible. Great success has been attained, and it is possible to transmit as many as forty-eight messages simultaneously over a single channel, with high efficiency.

As literature of this revolutionary development is for the most part confined to specialized technical journals issued by the great telecommunication corporations, Prof. Willis Jackson has supplied a real need by providing a convenient and reasonably comprehensive monograph on high-frequency transmission.

Power transmission engineers will be attracted by the title, but they will find little in the book which seems to relate to their everyday work of transmitting powers of the order of 100 MW and above over distances up to say 200 miles, unless they are prepared to go through the author's exposition in detail. If they do so, they will learn much that is of service in connexion with their more intricate problems, such as those involved in stability calculations, and in determining the effects of impressed voltage surges.

Telecommunication engineers, who must perforce remain acquainted with the 'telegraph equations', will be more at home with the author's methods, and should have little difficulty in bringing themselves up to date in the new field.

Prof. Jackson's method of exposition is essentially spartan. He gives only cryptic indication of what is actually achieved by the use of high-frequency transmission lines, and evidently expects that his readers should be satisfied to plunge into abstract study without being tempted by a recital of practical achievements. This omission will, in the reviewer's opinion, materially and unfortunately reduce the circulation of a valuable book. It should, however, be noted that among the miscellaneous applications mentioned by the author are metallic insulators for supporting circuits carrying very high frequency currents of constant frequency, a non-contact short-circuit, and a condenser which will pass direct currents. These are sufficiently startling to arouse interest in all thinking electrical engineers.

After an introductory chapter on applications of transmission lines at very high frequencies, the subject is developed in five main sections, namely, the basic equations for transmission lines propagating in the principal mode, the propagation characteristics of lines, the behaviour of terminated lines, resonant lines, impedance transformation—the use of the circle diagram technique.

Free use is made of differential equations and hyperbolic functions as a means of avoiding ponderous explanations, but clear and interesting physical explanations and comments are provided, wherever they are required.

Forty-four diagrams are included. Most of these are simple sketches such as might be drawn by a lecturer on a blackboard, and are of little permanent service. Those relating to the circle diagram are, on the contrary, clear and complete, and are potentially of great practical service, since accurate basic data are given to enable a serious reader to construct his own diagrams for definite applications. The style of writing is clear and interesting, but it is marred by an excess of 'verys' and phrases such as 'on the other hand'. The book is of convenient pocket size, and is a worthy addition to an excellent series.

COAL IN RELATION TO ATMOSPHERIC POLLUTION*

By DR A PARKER

Director of Fuel Research, Department of Scientific and Industrial Research

IN 1912, following an international smoke abatement exhibition in London, there was appointed an Advisory Committee on Atmospheric Pollution under the Meteorological Office. Later, in 1927, the work of this Committee was taken over by the Department of Scientific and Industrial Research. Under the guidance of the Atmospheric Pollution Research Committee of the Department, and with the co-operation of many local authorities, methods of measurement of different forms of atmospheric pollution have been improved and new methods devised, and systematic records of the extent of pollution in many parts of Britain have been obtained. The results of this useful work have been published in a number of annual reports of the Committee. Over a period of three years just before the War, an intensive survey of atmospheric pollution in Leicester was undertaken under the guidance of the Research Committee and a full report of this work is now in the press.

There is no doubt that all these activities have played their part in bringing about during the last fifty years a gradual but very definite improvement in many areas. There is much truth in the statement that the old type of London fog is now almost unknown. Much still remains to be done, however, before the air of our towns will be reasonably clean and free from smoke and other forms of pollution, and the ultimate goal will not be achieved except on the basis of intensive scientific research in several directions.

Quantity of Coal Used in Relation to Population

Before discussing the nature and the quantity of the polluting substances discharged into the atmosphere from the use of coal for different purposes, let us consider what changes have occurred in Great Britain since the beginning of the eighteenth century in the rate of production of coal, and in the relationship between the rate of production and the size of the population. This period is chosen because it was during the eighteenth century that there were the first signs of the beginning of the enormous developments in the use of coal which took place in the nineteenth century, particularly in the second half of that century. Great Britain has been fortunate in possessing reserves of coal of good quality and of many types. Early recognition of the possibilities in the use of coal for the generation of heat, power, and light, and the skill and enterprise of our scientific men, engineers and industrialists of 100-150 years ago, gave Great Britain a good lead in the industrial developments that followed.

The rapid rise in the use of coal was accompanied by a marked increase in the population. The great changes which occurred are indicated by the accompanying curves, which are plotted from estimates of the population and of the annual outputs of coal from the year 1700 to the early years of the present century.

The important changes in Great Britain during the last 140 years have thus included an increase in the annual output of coal from roughly 10 million tons to about 200 million tons, and a great increase in the population from roughly 10 to 45 millions, and the crowding of masses of people in large towns. Most of the coal brought to the surface in Great Britain is used in this country. If there had not been considerable improvements in the methods of using coal, atmospheric pollution from this source would certainly have been very much worse than it is to-day.

Efficiency of Use of Coal

In Table 1, figures are given to show the principal inland uses of coal in Great Britain and the quantities in millions of tons a year for the three-year period 1936-38.

TABLE 1 SOME USES OF COAL IN GREAT BRITAIN (ANNUAL AVERAGE FOR 1936-38)

	Purpose for which coal is used	Quantity in millions of tons
1	General use, including 40-45 million tons for domestic purposes	98
2	Electricity power stations	14
3	Coke ovens	20
4	Gas works	19
5	Railway locomotives	13
6	Collieries	12
7	Ships' bunkers, foreign and coastal	12
	Total	188

With what efficiency is the coal used for the various purposes mentioned above, and can the efficiency be increased? Unfortunately it is not possible from available data to do more than give very rough estimates of the efficiency of utilization of coal for the many purposes for which it is employed. The rough estimates that can be made, however, do serve as a useful guide.

Of the quantity of 98 million tons given in the first item of Table 1, approximately 40 million tons are used for domestic heating and cooking and 60 million tons by various industrial undertakings for such purposes as heating furnaces and raising steam for processes and for power. Though the efficiency of generation of steam in large boiler installations, the most modern type is often as high as 80 per cent, this high efficiency cannot be maintained unless the

* Substance of a Chadwick Public Lecture delivered on March 13

equipment is kept in first-class condition and is operated under close scientific supervision. In the past, coal has been relatively cheap, and in large numbers of industrial undertakings little attention has been given to equipment such as boilers and furnaces. Far too much heat, which could have been usefully employed in several ways, has been carried away in hot gases and liquids, and large quantities of steam have been wasted. With many furnaces of the kind used for heating metals, not more than 5 per cent of the heat value of the coal is put to useful purpose. It is difficult in furnaces of this kind to obtain high efficiency, but there is no doubt that appreciable improvement is practicable in many cases. As an overall figure, it is unlikely that the efficiency of use of the 60 million tons of coal included in the first item of Table 1 for industrial purposes exceeds 50 per cent.

On the domestic side, the overall efficiency of the open coal-fire under average household conditions is not more than about 20 per cent. The corresponding figure for the general purpose appliance in which coal is used for space heating, provision of hot water, and cooking is somewhat greater because of the heat taken up by the water, but it is probably not more than 25 per cent. Here is considerable room for improvement. Much effort is now being expended in signing open fires to provide not only radiant heat, but also convected heat derived from air which is heated by passage through ducts adjacent to the fire, the warm air is discharged into the room in which the fire is placed, or into other rooms. The probability that with systems of this kind the average household would obtain an efficiency of 30 per cent in place of 20 per cent with the ordinary open fire. During the past twenty-five years there has been great expansion in the use of electricity and a great increase in the efficiency of generation. The quantity of coal consumed annually during 1936-38 at electricity power stations was 14 million tons, this is more than twice as much as during the years 1921-23, and in 1943 the amount was about 23 million tons.

In 1921 the average quantity of coal consumed to produce one unit of electricity was 3.4 lb, whereas in 1938 it was only 1.4 lb. This means that the efficiency of generation was two and a half times as great in 1938 as in 1921. Even with this great improvement, the heat equivalent of the electricity generated was only about 20 per cent of the heat value of the coal burned under the boilers. Allowing for losses in transmission, the efficiency of generation and distribution in 1938 was about 18 per cent. Though the efficiency of generation is low the efficiency of utilization is usually high, for example, it may be taken as practically 100 per cent for the electric fire, this means an efficiency in relation to coal used at the generating station of 18 per cent. Before the War the efficiency of carbonization of coal in coke ovens and at gas works had reached the high average of roughly 75 per cent. Further improvement is probable but it clearly cannot be very great. From each ton of coal carbonized there is produced about 14 cwt of coke, 60-80 therms of gas, 10-15 lb of tar, and ammonia equivalent to about 1 lb of ammonium sulphate. At gas works, some of the coke is used to make water gas, heat the ovens, and generate steam and power, so that the quantity of coke available for sale is roughly 9 cwt per ton of coal. At coke ovens, a large proportion of the coal gas is used to heat the ovens. The coke is sold mainly for blast furnaces and other furnaces,

though some is sold for other industrial purposes and sometimes for domestic use. Much of the surplus gas is sold to gas works.

It is difficult to give an estimate for the efficiency of use of coke for the many and varied industrial purposes for which it is employed. Though it can be used with high efficiency in industrial boilers and for making producer gas, the efficiency with many furnaces is low. It is unlikely that the overall average is more than 50 per cent.

With coke for the open domestic fire with a grate suitable for burning this fuel, the efficiency under average conditions is roughly 25 per cent, and it could no doubt be increased to about 30 per cent, as with the open coal fire, if provision for heating by convection as well as radiation were included. In closed stoves and boilers (with hot-water radiators) of the usual domestic type, the efficiency of using coke is in the region of 50 per cent.

The efficiency of gas appliances in general is higher than with appliances using coal or coke. Modern gas fires have an efficiency of 40-50 per cent under average conditions.

In considering these figures for coke and gas, which are intended to represent overall average, not test, conditions, it should be remembered that in order properly to compare them with the figures for coal, they should be reduced to allow for the fact that heat is used and lost in making coke and gas from coal. If the efficiency of production is taken as 75 per cent, the efficiency in use should be multiplied by 0.75 to give the 'coal economy efficiency'.

Though much attention has been given to fuel economy by railway undertakings, the overall efficiency of use of coal for power for locomotives is necessarily low. Including shunting operations, the overall average is well below 10 per cent, and is probably not more than about 5 per cent.

Nature and Amount of Pollution

Of the various products of combustion or partial combustion, those which give rise to pollution of the atmosphere are mentioned in Table 2.

TABLE 2 POLLUTING SUBSTANCES FROM COAL AND PRODUCTS

(a) Solid	Particles of carbon causing black smoke and particles of mineral matter or ash carried forward with the gaseous products
(b) Liquid carbonaceous material	Fine particles of liquid tarry matter causing yellowish or brown smoke
(c) Unburned and partially burned gases	Gaseous hydrocarbons and carbon monoxide
(d) Sulphur oxides	Sulphur dioxide and some sulphur trioxide which with water forms sulphuric acid

It is not easy to assess the amounts of those forms of pollution produced by the various fuels with their different methods of use, and only approximate estimates can be given. It is worthy of note, however, that the methods of measuring amounts of pollution are steadily being improved. For example, during recent years considerable attention has been given at the Fuel Research Station of the Department of Scientific and Industrial Research to the measurement of the quantity of smoke emitted from domestic fires and industrial boilers using coal, and a satisfactory method has been devised. A detailed description of the method is being prepared for publication. It is based on measurements of the amount of light absorbed by the smoke-laden gases when a beam of light under standard conditions is passed through a layer of the gases, many difficulties had to be over-

come before a technique of sufficient accuracy and reliability was devised. As a result of this work, the figures now available are much more reliable than those previously obtained. Though the quantity of smoke emitted from the domestic fire is high, this latest investigation has shown that it is not so great as has often been stated.

In Table 3, approximate estimates are given, on the basis of the best available information, of the total amount of pollution produced annually from the use of coal in Great Britain under the conditions during the few years preceding the War.

TABLE 3 NATURE AND QUANTITY OF POLLUTION FROM COAL IN GREAT BRITAIN

Type and use of fuel	Quantity of coal (millions of tons per annum)	Pollution produced (millions of tons per annum)		
		Smoke	Ash	Sulphur dioxide
Coal				
Domestic grates	42	1.1	0.1	1.0
Electricity power stations	14	small	0.1	0.4
Railways	13	0.4	0.1	0.4
Collieries and various industrial uses	68	0.8	0.2	2.4
Coke and Gas				
Coke ovens and use of coke	20	small	small	0.6
Gas industry at gas works	19	small	small	0.1
in using gas		nil	nil	small
in using coke		nil	small	0.2
Total	176	2.3	0.5	5.0

From the figures in this table, the weight of tarry and carbonaceous matter in the smoke produced is 2-2½ million tons a year, or roughly 1½ per cent of the weight of the coal used. Approximately one half of this weight of smoke is derived from domestic grates, which use only about one quarter of the coal. The total pollution by oxides of sulphur is about 5 million tons a year, and the weight of the grit or ash discharged into the atmosphere is roughly 0.5 million tons. Not more than one fifth of the sulphur and grit arises from domestic appliances burning raw coal.

Reduction in Pollution

In the present state of knowledge and of development of fuel-burning appliances, it is not practicable entirely to prevent the pollution of the atmosphere through the use of coal and its products. It is practicable, however, to effect a considerable reduction in the amount of the pollution caused by smoke and grit, though it is much more difficult to reduce the amount of pollution from sulphurous gases. How can such an improvement be effected? There is no one method. Developments and changes in several directions are necessary.

In the first place, all practicable steps must be taken at the colliery to clean the coal before delivery to the consumer. A reduction in the adventitious mineral matter will reduce generally the solid matter to be removed when the coal or coke is burned, and the quantity of sulphurous gases discharged into the chimney. It is apparent also that as the best coal seams are gradually worked out the need for efficient cleaning will become greater.

The next important step is to ensure that the coal and its products, coke, gas and electricity, are used as efficiently as is economically practicable, and that the heat and power developed are not wasted. Efficient use of fuel can only be achieved as a result of skilled and intelligent operation, maintenance of fuel-using appliances in good condition, development of better

appliances, and the judicious application of insulating materials to reduce waste of heat. In Great Britain insufficient attention has been given to the training of fuel technologists and operators, and little attention has been given to the possibilities of insulating buildings with the object of conserving heat.

With large modern boiler installations equipped with mechanical stokers, little or no smoke need be produced, but installations of this kind with forced draught carry appreciable quantities of ash or grit into the chimney gases. Most of the grit can be removed from the chimney gases by the use of efficient grit-catchers such as have been installed at the largest electricity generating stations. There might well be extension of the application of this method to other boiler and furnace installations. At certain of the largest electricity power stations in thickly populated areas of Britain, coals containing not more than 1 per cent of sulphur are selected for firing the boiler furnaces. In addition, these power stations are equipped for the operation of processes which remove most of the oxides of sulphur from the chimney gases before discharge to the atmosphere. These processes of treatment to remove sulphurous gases, however, are not easily operated and are expensive, their cost on pre-war prices was 2-3 per ton of coal burnt. There is required some efficient but cheaper method of reducing the quantity of oxides of sulphur discharged, suitable not only for the largest but also for smaller boiler installations. This difficult problem is being studied, but there is no immediate solution in sight.

It has not been possible in the past, with the large numbers of hand-fired boilers at numerous industrial works, to avoid the emission of smoke, particularly for a time after stoking. As a result of extensive work by the Fuel Research Station during the last few years, equipment has been developed to replace the doors of marine and Lancashire boilers, whereby the emission of smoke can be practically eliminated. This equipment is simple to construct and very simple to operate. It provides at the right time and in the right way the extra air required to burn the smoke-volatile matter evolved from the fresh coal for the necessary period after stoking. This equipment is already in satisfactory use on many hundreds of marine boilers, and its value has been fully demonstrated, not only does it greatly reduce the amount of smoke, but also it assists in maintaining high efficiency in utilizing the heat value of the coal.

The domestic open fire produces more smoke per ton of coal burned than any other appliance in general use, it has already been mentioned that about one half of the smoke pollution arises from domestic appliances, though they consume less than one quarter of the total coal used, or less than one tenth of the coal burnt direct and not submitted to such processes as carbonization. Though the problem has been studied by many investigators, there is no immediate prospect of designing an open fire which will burn bituminous coal without producing a smoke. There are designs of open fire, however, which will bring about a reduction in the amount of smoke to about one half of that with the open fire of usual type, but they have not yet been tried in general use by the average householder. The emission of smoke during the early stages of burning after lighting seems to be unavoidable.

There is at present no method of reducing the amount of pollution by sulphurous gases from one ton of solid fuel burnt in domestic appliances.

whether the fuel is coal or coke, the proportion of sulphur in coke is roughly the same as in the coal from which it is made

Pollution by grit from the burning of coal and coke in domestic appliances is not easily prevented, though fortunately it is not very great

Substitution of gas for solid fuel would avoid pollution by smoke and grit and would reduce pollution by sulphurous gases to a negligible amount. The use of electricity in place of solid fuel avoids the production of smoke, but would not prevent pollution by grit and sulphurous gases unless the generating stations are equipped to remove the grit and sulphur from the chimney gases. In general, however, gas and electricity are too expensive for continuous heating in the average house, but they have advantages in many circumstances for short-period intermittent heating and for cooking

So far as domestic appliances are concerned it would seem that encouragement should be given to the use of coke, gas, and electricity in place of coal, so far as is economically practicable, if atmospheric pollution is to be greatly reduced. But the changes suggested could only take place gradually, if the demands for the various fuels and forms of energy are not to overstep the supply, and there must be a suitable balance if the resources of the different types of coal are to be used to the best advantage in the broad national interest. It should be pointed out that all the possibilities have not been covered. For example, the possibilities of communal central heating and district heating have not been discussed. It is hoped, however, that this broad review will serve to indicate the general lines along which progress can be made

COAL MINING IN GREAT BRITAIN

It would be difficult to exaggerate the importance of the Report of the Technical Advisory Committee on Coal Mining, presumably to be known as the Reid Report*. For almost a century, coal mining in Great Britain and its special aspects have been the subject of inquiry for royal commissions and departmental committees, and in the past few months much has been written on the reorganization of the industry. However, the Reid Report is without parallel. Seven distinguished mining engineers have examined the present lamentable position, and have set out in detail their proposals for the creation of a prosperous and efficient industry. Mr Reid and his colleagues have expressed their views with complete frankness, and have criticized impartially mine-owner, mining engineer and workman. If ever the term 'blue-print' could be applied to a document, then his report is a blue-print for the post-war mining industry in Britain.

The approach to the problem is historical, and part I includes a revealing comparison of the coal industry of Britain with those of the principal Continental nations. If two nations are mining coal under approximately similar natural conditions, then the output of coal per man-shift worked can be regarded as a measure of the efficiency of mining. Similarly, records of output per man-shift over several years will provide evidence of improvement or de-

terioration in the mining situation of a particular nation. In any comparison of statistics of output per man-shift careful account must be taken of the natural conditions under which the coal is worked. In the United States, mining conditions are greatly superior to those prevailing in Britain, and in Poland mining is carried on under the best natural conditions in Europe. However, in Holland and on the Ruhr, conditions are certainly no better than those of the British coalfields. Although useful conclusions can be drawn from the statistics of American mining, for a fair comparison we must turn to our Continental neighbours, and particularly to Holland and the Ruhr.

Those who desire an account of the vicissitudes of the British coal trade must refer to the report itself. The most significant period is that between the years 1927 and 1939, and it is sufficient here to say that, in spite of the introduction of several thousand mechanical coalcutters during the years 1913-27, output per man-shift showed little improvement from the 20.32 cwt of 1913 to the 20.62 cwt of 1927. Some progress was made in the years 1927-36, when the output increased by some 14 per cent to 23.54 cwt, a maximum for the period between the Wars. Small as the increase appears, it was achieved only as a result of intensive mechanization—the tonnage of coal mechanically cut increased from 58.5 to 142.2 million tons between 1927 and 1939, while the tonnage carried on face conveyors increased from 28 millions in 1928 to 134 millions in 1939. Taking Great Britain as a whole, the situation in the coal mines left little room for complacency.

In 1914 Britain was able to dominate the sea-borne coal trade of the world, and substantially retained this position until 1925, when Poland and Germany first assumed the position of serious competitors. To compare British and Continental progress the Committee has adopted as the basic year that in which each country attained the 1913 level of output per man-shift, and the following table is extracted from the report:

Country	Basic year	Output per man-shift		Percentage increase
		in basic year cwt	in 1936 cwt	
Poland	1927	23.44	36.20	54
Holland	1925	16.48	35.94	118
The Ruhr	1925	18.62	33.66	81
Britain	1927	20.62	23.54	14

Comparison with the United States would be unjustified, but it should be noted that the output per man-shift in the American bituminous mines amounted to 93.8 cwt in 1939.

Many reasons are advanced for this failure to attain, or even approach, Continental standards of output. The British industry has long lacked the financial resources to undertake major long-term improvements, and considering the low average profit per ton—7d. during the years 1929-38—this is not surprising. Conditions of mineral ownership have proved a disastrous handicap to the mines of Britain. Until 1942 the minerals were privately owned, and there remains a legacy of small and awkwardly shaped leaseholds, worked by an excessive number of mines, many of which are of low capacity. On the Continent the amalgamation of undertakings has resulted in the concentration of production in large well-equipped mines. In 1938 the Ruhr mines were of an average capacity of 778,000 tons per year,

* Ministry of Fuel and Power. Coal Mining. Report of the Technical Advisory Committee (Cmd 6610). Pp ix+150 (London: H.M. Stationery Office, 1945). 1s. net.

the twelve mines of Holland averaged 1,200,000 tons per annum. Britain, too, has mines of large capacity, but there are many small mines. In 1943, 90 per cent of the output came from 816 mines owned by 353 separate undertakings. The average yearly output per mine was 228,000 tons.

Relevant as are the above and other important conclusions, the recommendations on the details of practical mining form the backbone of the report. The hidden complexities of underground mining make the discussion of this section no easy task, and it is proposed to emphasize two fundamental operations—those of getting and transporting the coal. In Britain, most of the coal seams are worked by the 'longwall advancing system' of mining—some 74 per cent of the collieries are so laid out. Less popular, but giving good results under certain conditions, are the 'room and pillar' and 'longwall retreating' systems.

The room and pillar system was an early development in British mining practice. Here the seam is first divided into pillars of side 20–50 yd., by driving two sets of roads at right-angles. Developed a century ago in the coalfields of Northumberland and Durham, the method gives best results in shallow seams of a suitable thickness, say, 5–6 ft. When, however, attempts were made to work the deeper seams by room and pillar, many difficulties were encountered. Because of the great pressure on the pillars, there was an excessive 'crush' on the workings, the pillars tended to disintegrate, and the roads to close in. Pillar extraction, a normal and safe operation at shallow depth, was made difficult and often impossible. The system also proved unsuited to the working of thin seams, and there was thus a gradual change over to the 'longwall' system of working. However, the room and pillar system is almost universal in the United States—with the important difference that the workings are highly mechanized. Since 1941, American methods of production have been studied by British engineers, and it is considered that a proportion of the British output could, in future, be won from mechanized room and pillar workings. Experimental lay-outs have been equipped on American lines, and the results are sufficiently encouraging to suggest that the system will find a useful, if limited, application in Britain. The outstanding feature of American methods is that a very high proportion of the workers is engaged on actual coal production, and this accounts in some measure for the high output per man-shift.

Natural conditions in Britain have proved most suited to the 'longwall advancing' system. In its modern application a straight wall of coal or 'face', say, 200 yd long, is prepared. Two mechanical conveyors are laid along the face, each feeding on to a main conveyor in the centre and at right-angles to the face. The coal worked is filled on to the conveyors, and loaded on to 'tubs' (small wagons) at a loading point at the end of the main conveyor. An average rate of advance is 5 ft per day—that is, a block of coal 200 yd long, of height equal to the thickness of the seam, and 5 ft in depth is removed. The whole of the equipment and supports must thus be advanced 5 ft per day. More important, the empty space, or goaf, left behind the advancing face, must be partially packed with debris, and roads must be prepared and maintained through the goaf. This is unproductive work, inherent in this system of mining, and absorbs the labour of substantial numbers of underground workmen. Nevertheless,

the method has many technical advantages, and will long find an important place in British mining practice.

The 'longwall retreating' system combines, in some measure, the advantages of the other two systems. Roads, known as headings, are driven in the seam to a pre-determined boundary to form a pillar, say, 300 yd long and 100 yd wide. This pillar is then extracted back towards the main road from which the headings were started. So far, the system has not been widely used in Britain, but there are reasons to believe that, with the use of modern machinery for intensive development, longwall retreating could well be applied in many British mines, with a consequent reduction in the proportion of unproductive labour.

The Committee thus recommends a complete reconsideration of established mining methods. Mechanized room and pillar should be applied where conditions are sufficiently favourable. Since this will by no means be generally applicable, consideration should be given to the use of longwall retreating methods, and finally the longwall advancing system should be applied to those circumstances in which the other two systems are unsuitable.

In the nineteenth century, practically the whole output of British mines was won by means of the hand pick. Now some 80 per cent of the coal is under cut by mechanical coalcutters. After undercutting holes are bored in the coal, and these charged with explosive and fired, so leaving the coal in a suitable condition for hand filling by means of a shovel. In 1939, on every working day, nearly 1,000,000 tons of coal came from the shovels of the British miners. If the operation of loading could be mechanized, there are clearly possibilities of a tremendous saving in labour. For room and pillar work there are excellent machines of British and American manufacture, used for lifting the broken coal from the floor to a conveyor or tub. Loading machines of a different type are required for longwall faces, and the design of a suitable machine is a difficult technical problem. Nevertheless, British manufacturers have produced loading machines of distinct promise, and these are in use in experimental installations. That the Committee attaches the greatest importance to their further application is clear from the statement "the development in mining technique must be directed first and foremost, to a reduction in, and ultimately to the practical elimination of hand loading."

A mechanical loader, however efficient, has one important limitation—a coalcutter must first be used to prepare the coal for loading, and the use of explosives may also be necessary. The Committee envisages the use of machinery which will be capable of simultaneously cutting and loading the coal. At least one machine of this type has been used, and the prototypes of other machines are nearing completion.

Traditional haulage practice provokes the keenest criticism. In British mines there is apparently serious wastage of labour in hauling the coal from the working face to the shaft bottom. One haulage worker is required for every 50 tons of coal produced in the United States, for every 20–25 tons in Holland, and for every 5 tons in Britain. There is evidently much to be learned from a study of American and Continental haulage methods.

Wire-rope haulage is standard practice in British coal mines. Conveyors may be used to bring the coal to a loading station, and from there the tub

hauled to the shaft by means of wire ropes driven stationary engines. In an old or badly laid-out mine, the coal may be hauled by a succession of such haulages, each haulage requiring its complement of haulage engines. Conveyors could be much more widely used to transport the coal to well laid-out loading stations, so eliminating the wasteful use of labour and subsidiary haulage systems.

In the United States and on the Continent, locomotives are widely used underground. But the use of locomotives requires roads which are level, or nearly so, and the present lay-out of most British mines is such as to prohibit their widespread installation. Roads have been driven in the coal seams, but in general the gradients are unsuited to the use of locomotives. Continental seams are more inclined, and the practice there is to drive level roads through solid strata, these serving as the main arteries of the mine along which the locomotives operate. The organization for locomotive haulage will require the preparation of great lengths of graded roadways, and if the full advantages of locomotive haulage are to be realized, mine cars of a high capacity will be required. The capacities of the tubs used in British mines range from 3 to 28 cwt—the average is probably 12 cwt. For use with locomotives, mine cars must be required each capable of holding several tons of coal.

For details of mining practice are passed over in this unique survey. Standards of mine lighting, the Committee considers, could be materially improved. The advantage to production, safety and health of illumination at the coal face is now provided by portable self-contained lamps, but it is recommended that power-fed lighting should be installed at the coal face. Recent research has shown that the cathode discharge lamp may well prove a more efficient and efficient means of illuminating underground workings.

In an interesting paragraph the appearance of very premises is discussed. It is true that in the past little or no attention has been paid to this point, and "disorder and dilapidation" so often associated with colliery premises must have its psychological effects on the workmen and adversely influence public opinion on the state of the industry. An architect should be consulted when plans are being prepared for new mine or for remodelling an old mine.

It is apparent that reform on the lines suggested in the Reid Report will require major changes in the organization of the coal-mining industry in Britain, and this is discussed under "Conditions of Work". There will need to be amalgamation of many of the smaller undertakings to form productive units of a much greater capacity, and many existing mines will become redundant. There is a note of warning to the workmen and their leaders that if living wage-levels are to be maintained, then there must be a considerable increase in output per man, and that a rebuilt industry may have to disperse with substantial numbers of unskilled workers. In the past, the layman may have formed the view that Britain's coal problem was that of utilizing her abundant resources of coal. This report puts first things first—the fundamental problem is that of mining the coal efficiently, and any plans for the utilization of coal depend primarily on the availability of large quantities of cheap coal. Finally, those with no special knowledge will read the report without difficulty, assisted by a most useful glossary of mining terms.

H. HARTLEY

IT is a commonplace of criticism that a painting is not only the result of the artist's competence and temperament, but also of his country and period. Thus a Titian could arise nowhere else than in Italy, neither could a Vermeer be found elsewhere than in the Low Countries. The former reflects the warm colouring of the south, and the patronage of opulent, semi-pagan princes and prelates, whereas the latter echoes the cooler skies of the north, and the solid worth of prosperous burgherdom. Some years ago, Frank Rutter, following an earlier suggestion by Sir Michael Sadler, pointed out that, from the commencement of the present century, art in the hands of its more advanced exponents became more and more violent until, in the last years before 1914, men like Kandinsky and Wyndham Lewis were painting pictures of which the themes were connected in some way or another with war.

This prophetic aspect of the psychology of art can best be realized after study of pictures extending over some years, and it may be that the six war-time exhibitions of the Royal Academy do not constitute a long enough series, but one point in particular has attracted my attention, and to add emphasis I propose to illustrate it by reference to pictures painted by academicians, or associates, that is, to the work of men who, traditionally, are not included among the most advanced members of the craft.

Consider, first of all, Algernon Newton, who in 1942 exhibited bright and sunny scenes of London's canals. As the years have passed, his sunshine has gradually become less bright and more gloomy until in the present exhibition, even in pictures of the countryside (Nos 348, 352, 363), it has achieved that blackish quality which gleams out fitfully before the storm, and in the town has become so dramatic as almost to be theatrical (No 68). Sir Alfred Munnings is another whose sunshine is sometimes gloomy (No 140) and whose skies are often sad (Nos 136, 140). On the other hand, Edward Wadsworth has two longshore scenes (Nos 711, 715) of a type sufficiently advanced to satisfy any but the most fervid worshipper of 'isms'. His colours are strong and the first impression is one of stimulus akin to that of a cocktail, but the stimulus soon passes and a vague feeling of malaise, as it were a sense of the malevolence of the inanimate, remains. These might be thought a curious sequence and combination to occur as a long and hard-fought war drew slowly to a victorious close, but they are not unintelligible when considered in relation to the gradual realization of the thorny problems which would beset the peace-makers.

A painter's problems are exemplified by the work of James Fitton. "Woman Reading" (No 61) and "Country Interior" (No 602) belong to a group of works which he has shown during the last few years, and which are chiefly exercises in the management of red, perhaps the most difficult of all colours except purple, of which more later. These two canvases show, as they were bound to do, how the primary colour, red, tends towards its secondaries (orange and purple) and the secondaries towards the tertiaries, or, if this theory of colour be considered too old-

fashioned, they may be regarded as essays in the harmony of orange and red, and the employment of suitable contrasts and discords. So far as one may judge from the background of "Reclining Figure" (No 678), the artist himself would prefer the latter theory.

Purple in its lighter tones has ruined many acres of canvas in pictures of the 'sheep-among-the-heather' type, but in its deeper tones it is rich and magnificent, though still dangerous. The State portraits by Gerald Kelly (Gallery III) are noteworthy for the skill with which the imperial purple is rendered, a skill which cannot be fully appreciated without the realization that instead of the usual foils of green and brown these great masses of colour are displayed in a setting of parian coolness, and yet never for one stroke of the brush does the colour get out of control. True, the gold embroideries are a help in achieving this end, but they are by no means the whole of the story.

On an adjacent wall in the same gallery, "Dr Clive Forster-Cooper, F.R.S., Director of the Natural History Museum", by Meredith Frampton (No 165), blends complete mastery of the painter's materials with consummate draughtsmanship. For the former, reference may be made to the contrast in texture between the surfaces of the dog's jaw in the left lower corner and of the series of plaster models of some upper molars of primitive mammals scattered over the table in seeming disarray, while the drawing is summed up by the open book in which is epitomized a whole course of perspective and line. Another excellent portrait hangs in the far corner of the same room. It is L. Campbell Taylor's portrait of "The Rt Hon the Lord Macmillan, G.C.V.O., LL.D." (No 205), whose voluminous black robes, set against deep green curtains, are relieved by an edging of silver lace. A more intimate type of portraiture is "Professor A. G. Tansley, F.R.S.", by W. G. de Glehn (No 302), in which the sitter is shown, pipe in hand, in the quiet of a book-lined study.

Of the war pictures, "Torpedoing of the *Turpitz* by Midget Submarines" by Richard Eulich (No 569) gave me most pleasure. No minefields, even in the clear waters of the Norwegian fiords, were ever so visible as these—never was there such a whelk as crawls on the bottom of this sea, yet all have their place in this picture, and no one would wish them away. Whether or not we have here an echo of the Futurist 'plastic interpenetration of matter' I neither know nor care, drawing, design and painting are all good, and the picture pleases me.

As usual, the sculpture is a very mixed lot. To the zoologist the more or less naturalistic works such as "Tarka", by P. E. Norman (No 1248), "Leopard" by Hermon Cawthra (No 1281), and "Rhesus Monkey" by Josephine Hunt are the most attractive, and he will probably find that most of the horses are better than usual. On the other side of the account he will put "Long-nosed Hedgehog" (No 1293), if only on account of the unpleasant colour of the marble, as well as the lumpy "Messenger" (No 1359) and the brutish "Infant Dionysus". One cannot complain of the stone in which the two last are worked, it successfully conceals the sculptures.

The architectural exhibits are fewer than last year. In the main they are pleasantly uninspired, but two of them call for particular comment. "Durham City Replanned", by Thomas Sharp (No 1201), is ambiguous. If the new buildings in the foreground are really meant to be of the boot-box style, then

the incongruity between them and the castle cathedral in the background is so violent as almost to be bad manners and not merely bad art, if, the other hand, they are mere symbols to indicate where new building will be necessary, one must defer judgment until the designs for the actual buildings have been produced. The other doubt case is Sir Giles Gilbert Scott's design for the Coventry Cathedral, of which the interior does strike one as suitable for an ecclesiastical building, neither does it appear to be in keeping with the exterior.

Taking the exhibition as a whole, it is lively, varied, and of good quality. To expect it to indicate a definite trend in any particular direction, or favour of any one school, is unreasonable, since to do so would be to upset the general balance of the whole, but any visitor with some knowledge of the development of European art during the past 100 years will say of the Royal Academy, as was said of another body on an earlier occasion, "E pu muove".

OBITUARY

Sir Napier Shaw, F.R.S.

SIR NAPIER SHAW, whose death occurred on May 23, was born on March 4, 1854, in Birmingham, son of Charles Thomas Shaw, manufacturing engineer and jeweller. He was the sixth child of a family of eight, four brothers and four sisters. He married in 1885 Sarah Harland, lecturer in mathematics at Newnham College and daughter of Thomas Harland of Salford.

Shaw received his school education at King Edward's School in his native city, and throughout his long life retained a lively interest in his old school, serving on its governing body for many years. In 1872 he won a scholarship to Emmanuel College, Cambridge, and went into residence with the avowed intention, as he often told his friends, of entering the Indian Civil Service. He read mathematics, coached under Routh, and was 16th Wrangler in the Tripos of 1876. Later in the same year he obtained a class in the Natural Sciences Tripos, with distinction in physics. In the following year the College elected him to a fellowship and that seems to have been the end of the suggestion to embark on an administrative career in India. Cambridge was to be his home for the next twenty-two years apart from a short time spent in Berlin, working under Helmholtz.

Shaw soon made his mark in college and university. Lord Rayleigh appointed him demonstrator of the Cavendish Laboratory, jointly with R. T. G. Brook, and to that combination we owe the "Practical Physics" which became a standard text-book for schools and colleges up and down the country. Whatever experimental work formed part of the physics course. He gave up the demonstratorship in 1880 to become University lecturer in experimental physics and in 1898 was appointed an assistant director of the Cavendish. His early scientific work was a series of lines that have little connexion with what we now call his life work. His first published paper (*Cambridge Phil. Soc.*, 1879) dealt with experiments with mercury electrodes, and was followed a few years later by one in the *Philosophical Magazine* on the atomic weights of silver and copper. Miscellaneous papers on various subjects followed. Ventilation

subject in which he took an early interest which persisted throughout his life. In the course of his career he was asked to advise on the ventilation of many public buildings, among them the House of Commons, the Stock Exchange and the Metropolitan or-law schools.

The first contact Shaw made with official meteorology came in the form of a request from the Meteorological Council to prepare reports on the performance of evaporimeters in current use and on the more general question of hygrometric methods. The latter report was published in the *Philosophical Transactions* in 1888 and was the first contribution from Shaw's pen to the Royal Society's publications. His reputation in the scientific world was advancing rapidly and was recognized in 1891 by election to a fellowship of the Royal Society. He was a frequent attendant at the meetings of the British Association. In his later years he was to act as president of Section A in 1908 and of Section L in 1919.

While at Cambridge, Shaw took a very active part in the affairs of college and university. At Emmanuel he held the offices of steward, tutor and senior tutor (90-99), and a long list of pupils has to thank him for his kindly guidance and wise advice. Two important new movements in the University organization stand to his credit. In 1892 he was the prime mover in founding a group of colleges to combine their scholarship examinations and thus abate the competition of the most promising candidates which had become a source of embarrassment to tutors, school-masters and candidates alike. His second opportunity came towards the end of his time at Cambridge. As tutor, Shaw had repeatedly come up against the difficulty of pupils experienced in getting a start in life after leaving their degrees. Apart from an agency which confined itself to scholastic appointments, there was no machinery for helping them. There was an obvious opportunity for beneficial work for an office or agency that would make it its business to find out what openings were available in commerce, industry, Government service, and on the other hand would arm itself as fully as possible of the qualifications and competence of young graduates seeking employment. A certain amount of crusading to induce prospective employers to take graduates lacking *ad hoc* business experience into their service was also a missing field of activity. Shaw set out to enlist support for a scheme on such lines both within and outside the University. On the commercial side he received valuable assistance from the late Nathaniel Brown, a member of the London County Council, whose wide business connexions enabled him to suggest many useful lines of approach. As a result of these efforts, a Cambridge Appointments Association was started in 1899. It was eventually formally incorporated as part of the official organization of the University under the name of the Cambridge University Appointments Board.

Shaw left Cambridge towards the end of 1899 to become secretary of the Meteorological Council, which was about to become vacant through the retirement of R. S. Scott. The change involved some personal sacrifice, but his early work for the Council aroused his interest, and in 1897 the Royal Society had appointed him a member of the Council. In Shaw took charge, the Meteorological Office was at a low ebb. Strachey and Buchan, the two most active members of the Council, were advanced in years, and the drive which they and men of the

calibre of Stokes and Galton had put into the scientific work had spent itself. The staff consisted largely of middle-aged and elderly men who had been attracted to the subject as youngsters, but now found themselves carrying on their routine on salaries that were certainly not generous and with no superannuation to look forward to. Nevertheless, Shaw soon gained the unstinted loyalty of his staff and rekindled their interest. One of his first administrative tasks was to bring into operation a superannuation scheme for the clerical staff, even though it had to comply with the Treasury's instruction that if the Council felt it must make some provision for staff who had long and faithfully served them, it, like other employers, should see what it could do from its available resources. Recruitment of new staff also required much thought. Great care was exercised in the selection of junior clerks as vacancies arose, and gradually new posts were created that could be offered to graduates. By the time Shaw left the Office it had a considerable graduate staff.

In 1905 Shaw secured an overhaul of the constitution of the Meteorological Office. The Council, which had been responsible to the Royal Society, was replaced by a committee directly responsible to the Treasury, with himself as chairman of committee and director of the Office. The design of the new premises in Exhibition Road, South Kensington, to which the Office moved in 1910, took up much time during the following five years. It must have been a source of regret to Shaw that the building on which he had lavished so much thought and embellished at some personal expense should so soon prove inadequate to house all the activities of the Office. At the time of its design the top floor, to be occupied temporarily by the administrative staff of the Science Museum, seemed to offer ample space for expansion.

Under Shaw's vigorous guidance and the pressure of events, the activities of the Office increased rapidly. On the climatological side the network of voluntary stations that supplied reports to the Registrar-General and also those associated with the Royal and the Scottish Meteorological Societies came under the control of the Office. Summaries for all stations were included in the *Monthly Weather Report*, which thus became an index of the climatological information available in Britain month by month. Later on, but not until 1919, the British Rainfall Organization was absorbed. Kew and Eskdalemuir Observatories were transferred and with them came responsibilities for terrestrial magnetism, atmospheric electricity and seismology. The demands of aviation for meteorological help were beginning to press. With R. T. Glazebrook (the close co-operation, started in the early days at the Cavendish, continued up to the time of Glazebrook's death) Shaw started the Advisory Committee for Aeronautics, which brought much grist to the mill. With J. S. Owens's assistance, the work of the Committee on Atmospheric Pollution was got going. In the sphere of international meteorology Shaw also became a figure of importance. His election to the International Meteorological Committee on becoming head of the Office was little more than a matter of form, but in 1906 he succeeded Mascart as president of the Committee, an office he was to hold until 1923.

Despite the pressure of administrative work and of calls incidental to his position, Shaw found time for authorship and for making his contribution to the science of meteorology. In 1911 appeared the first edition of "Forecasting Weather", in which he

set himself the task of bringing together the physical laboratory and the daily weather. His contributions in the form of papers and articles covered most aspects of the subject and are too numerous for individual mention here, but we may perhaps single out "The Life History of Surface Air Currents", in which the method of using synoptic charts to construct trajectories and so trace different air supplies to their origins was developed. It led up to the modern ideas of air-mass analysis which have yielded such valuable results, both theoretical and practical, through the labours of the Norwegian school of meteorologists.

Shaw's influence went far beyond the immediate output of his pen. He was a great advocate of a rational system of units, and never tired of ventilating the subject. If some of his efforts in this direction, such as the use of the absolute or tercentesimal scale of temperature which he introduced into the "Observatories' Year Book" and followed in his later scientific writings, have found few imitators, he had the satisfaction of seeing the millibar, first advocated by V. Bjerknes, find wide acceptance. After Shaw had introduced it in the British *Daily Weather Report* in the issue of May 1, 1914, other services followed suit, and its use is now firmly established in the international exchange of synoptic data and in upper air work.

The need for investigating meteorological problems on a world-wide basis led to another of his successful crusading efforts. Backed by the late Sir Norman Lockyer, he induced the International Committee to form a "Réseau Mondial Commission", and what is perhaps more important, he managed to arrange for the Meteorological Office to act for the Commission and collect monthly summaries on a basis of two stations to each square of 10° of latitude and longitude and publish them in annual volumes, thus providing raw material for investigations on seasonal forecasting and kindred problems by many workers. About the turn of the century, when Shaw took charge of official meteorology in Britain, the investigation of the upper atmosphere by means of kites and balloons was opening up a new field of research and turning meteorology from a two-dimensional into a three-dimensional science. Shaw saw to it that Britain played its part in the new field. Much of his work was done in association with the late W. H. Dines, whose home, transferred successively from Oxshott to Pyrton Hill and thence to Benson, became more or less a branch establishment of the Office. Not least among Shaw's gifts must be reckoned his power to interest others in his work. To that we owe the contributions of men like C. J. P. Cave and P. Y. Alexander to upper air research.

All these activities were rudely interrupted by the outbreak of war in 1914. It was not long before the Fighting Services felt the need for meteorological help, and new and unexpected demands were made on an Office struggling to maintain its essential routine. A greatly increased staff had to be recruited and hurriedly trained, and that raised a difficulty of its own. There was no suitable text-book on which to base the training. The writing of a comprehensive manual of meteorology had long been one of Shaw's ambitions and from time to time he had discussed ways and means with the Committee and found them sympathetic, but leisure for starting the work had been lacking. The desire had now become an urgent need, which the Committee met by suggesting that

Sir Henry Lyons should take over the day-to-day administration, as acting director, thus setting Shaw free for the labours of authorship. The arrangement came into operation early in 1918, the Treasury having given its consent and marked its approval by appointing Shaw scientific adviser to H. Government on meteorology. To meet the more urgent demands work was started on Part 4 of the full scheme, which presently appeared, though not until after the cease fire had sounded, under the sub-title "The Relation of Wind to the Distribution of Atmospheric Pressure". Lyons retired from acting directorship soon after hostilities ceased and Shaw had to resume full control up to the time of his own retirement in September 1920, and so fell to his lot to carry through the transfer of the Office to the Air Ministry. In anticipation of his earlier retirement he had consented to become president of the Royal Meteorological Society for the two years 1919 and 1920, a post he had consistently refused when asked to serve during the earlier years of his directorship.

Shaw left the Meteorological Office to become its first professor of meteorology in the Imperial College of Science and Technology. It had always been his ardent wish that universities in Britain should take part in the teaching and development of meteorology and for some years he had been reader in meteorology in the University of London. The new post was considerably further in meeting his desire. True, it was not a full professorial chair, but it was at least a beginning. He held it until 1924, when he succeeded by Sir Gilbert Walker.

His teaching post was not the only call on his time. The Atmospheric Pollution Committee pressed him to continue to act as its chairman, and the Ministry of Agriculture invited him to preside over a committee appointed to foster agricultural meteorology. Even more exacting were the calls of international work. Meteorologists were among the first to get together again after the War of 1914-18. An open conference was held in Paris in the autumn of 1919, and Shaw was the obvious person to act as president. The conference reappointed a permanent committee with Shaw as president. He was re-elected in 1921 despite the fact that he was no longer director of a national service. His release from the office did not come until 1923. The Upper Air Commission also insisted on Shaw becoming its president, that offered further opportunities for impressing ideas—or should it be ideals?—on meteorology. Among the tasks which the Commission sets itself is the publication of data collected on a world basis on 'international days'. Before the War of 1914 the issue of this publication was in German hands. It was decided to resume operations by printing information available for 1923. Shaw presented it in a *de luxe* style. He intended his volume to serve as a model of what the Commission should aim at. Unfortunately, *éditions de luxe* are expensive. The Commission was able to print the data for 1923 in a somewhat similar form, but for subsequent years Prof. Hergesell, who again became president when the Commission met in Leipzig in 1927, fell back on the expedient of setting it out in code.

Shaw's work for the Upper Air Commission gave us the tephigram, a diagram for plotting data from balloon ascents in which entropy and temperature are used as co-ordinates. It lends itself to rapid plotting, and the resulting graph, considered in relation to the grid, shows up regions of pressure

tial instability very clearly. The form is now in regular use in the forecast service of Great Britain and other countries.

During the years that followed his retirement from the Meteorological Office, the newly formed International Union of Geodesy and Geophysics also made calls on Shaw's time. He became president of its Meteorological Section and acted in that capacity at the meetings in Rome (1921), Madrid (1924), Prague (1927) and Stockholm (1930).

When he retired from his professorship, what Shaw himself regarded as one of his most important tasks still lay before him, the completion of the "Manual". A serious illness in 1928 threatened to prevent the fulfilment of his hopes but he lived to see all four volumes completed. The last, a revised and enlarged edition of Part 4, now with the more concise title "Meteorological Calculus. Pressure and Wind", was signed for press on March 31, 1931, when Shaw had entered on his seventy-eighth year. Even then his capacity for writing was not exhausted. In 1933 he gave us "The Drama of Weather", a

fascinating book addressed to the general reader rather than the specialist. Three years later a revised edition of Vol 2 of the "Manual", bringing up to date the statistical information, was called for. He signed the preface to this on March 4, the eighty-second anniversary of his birth. Two years later, when a second edition of the "Drama" was required, he still had the vitality to make considerable additions.

Shaw was the recipient of many honours. He was knighted in 1915. Honorary degrees were conferred on him by the Universities of Aberdeen, Edinburgh, Athens, Dublin, Harvard and Manchester, and foreign membership by the Academies of Boston, Oslo, Rome and Stockholm. His gold medals included the Symons Medal of the Royal Meteorological Society (1910), the Buys Ballot Medal of the Dutch Royal Academy (1923) and a Royal Medal of the Royal Society (1923). He was an honorary fellow of the Royal Society of Edinburgh and of Emmanuel College, Cambridge. He was made Commander of the Order San Tiago da Espada (Portugal) in 1921.

R G K LEMPFERT

NEWS and VIEWS

Prof C Leonard Huskins

PROF C LEONARD HUSKINS, professor of genetics in McGill University, has been appointed professor of botany in the University of Wisconsin, in succession to Prof C E Allen, who is retiring. Prof Huskins' appointment takes effect from September 1. Prof Huskins was born in Walsall, England, in 1897, he went to Canada with his parents at the age of ten, and was educated at Red Deer, Alberta, and the University of Alberta, Edmonton, obtaining the degrees B Sc Agr in 1923 and M Sc in 1925. As Overseas Scholar of the Royal Commission for the Exhibition of 1851, he went to the University of London (King's College) during 1925-27, when he obtained a Ph D in botany. He was then research cytologist at the John Innes Horticultural Institute until 1930. In 1930 he was appointed associate professor of botany in McGill University. Then he established the Department of Genetics and was appointed professor of genetics in 1934. Prof Huskins has worked chiefly on the cytogenetics of cereals and liliaceous plants, the origin of species through polyploidy and on chromosome structure. At the University of Wisconsin his teaching and research will be devoted mainly to cytology.

Academy of Sciences of the U S S R Anniversary Commemoration

THE Academy of Sciences of the U S S R celebrates this year the 220th anniversary of its foundation by Peter the Great. At first the Academy was not only a learned society and centre of research, but also a university or public school where Russian youths were trained for various vocations and even crafts. The first scientific debate was held at the Academy in November 1725, when Newton's theorem on the spheroidal shape of the earth was discussed. In 1745, that is, twenty years after its foundation, Mikhail Lomonosov, famous chemist, geographer and poet, whose work had an important bearing on modern science in most varied fields of knowledge, was

elected to the Academy, where he founded a chemical laboratory. Peter the Great gave the Academy his private library, which formed the basis of the present library, now numbering about ten million volumes. The Academy also received Peter's famous "Kunst-kammer" with its great collection of fossils, mineralogical specimens and curios, which in time developed into the present geological, zoological, mineralogical and palaeontological museums. Almost on his death-bed Peter drafted a plan for an expedition to Kamchatka to discover whether Asia and America were connected by land. The exploration of Russia and the study of its mineral, plant and animal resources played a large part in the scientific activities of the Academy at its inception. Its geographical department produced a series of maps of Russia and Siberia.

To commemorate the anniversary of its foundation, the Academy held a special session during May 25-June 6. The programme included meetings in Moscow and Leningrad, visits to various research institutes, and sight-seeing expeditions. More than a thousand guests from at home and abroad were invited. The session was opened by the President of the Academy, Vladimir Komarov, who spoke on the growing importance of the Academy. Papers were read on the history of Russian science in various fields and on the part played by Russian scientific workers during the War, and the contribution which they hope to make towards rebuilding the world. The geographical and geological expeditions of the Academy were the subject of special reports, as was the work of Russian men of science in the fields of organic chemistry, aerodynamics, mechanics and physiology. The problems now under investigation in the twelve departments of the Academy were discussed. The programme provided for a visit to the site of the famous Pulkovo Observatory, which was destroyed by the Germans. There was an exhibition of standard works printed by the Academy or written by its professors and published elsewhere. Some interesting manuscripts and other documents illustrating the history of the Academy were reprinted for the anniversary.

Journal of Meteorology

ONE result of the War has been such an increase in the number of meteorologists in the United States that the American Meteorological Society has decided that the moment has arrived when a financial success can be made in America of what is described as "a technical journal of the highest caliber in the field of meteorology". The recently reorganized Society has recognized the need to serve both the professional and amateur meteorologist, and it is for the professional that the new journal under the title *The Journal of Meteorology* is mainly intended (American Meteorological Society, Milton 86, Mass.) It is to be a quarterly journal eventually, but owing to the difficulty of starting a new publication, especially in war-time, it was considered best to have only two issues in the first volume, dated 1944, and the copy of the first issue that we have received, dated September 1944, is accordingly described as vol. 1, Nos. 1 and 2. The journal is edited by Prof. Victor P. Starr, of the University of Chicago, and there are four associate editors, among whom is J. Bjerknes. The print is larger than that usually used in scientific journals at the present time, and both it and the diagrams are very clear, the paper cover is a bright yellowish-orange. There are four articles, dealing respectively with the theory of the genesis and movement of cyclones, the determination of normal regions of atmospheric heating and cooling, the changes of temperature during the formation and dissipation of stratus cloud on the Californian coast, and lastly, the relationship between the major changes in the paths of tropical storms and the upper wind-field. The journal has certainly made a very promising start, and we wish its editors every success.

Planning Regional Electricity

IN devoting its April issue to "Electricity in its Regional Setting" the *Architectural Review* has rendered a real public service. The review of the whole situation, including recent public inquiries at Durham and Lincoln, the work of the Electricity Commissioners, the Central Electricity Board and the newly formed North of Scotland Hydro-Electric Board, which the Association for Planning and Regional Reconstruction has produced for this issue is admirably presented and is not only of particular interest to the scientific worker but also to every citizen concerned with the development of national resources and the preservation of amenities. Taken as a whole, it explores the shallowness of the pretensions of hydro-electric schemes for the Highlands to have anything in common with the ideas and procedure of the Tennessee Valley Authority, and it is strong indictment of the Government's persistent refusal to deal with the question of a real central planning authority.

The survey puts the case for a plan for electricity in its wider regional setting from various points of view and shows how profoundly unsatisfactory is the present situation. There has been no published survey, on the national and on the regional scale, of existing facilities and resources, and there is no evidence that the development of the electricity "Grid" has been anything but piecemeal. No published plan has seriously attempted to link together the ascertained physical facts—mineral resources, rainfall, communications and transport, population, consumption, etc.—with the proposed extensions and development. The Tummel scheme, as Lord Malcolm Douglas-Hamilton shows, is a glaring example of this omission

Again, apart from the national and regional aspects, the siting of both thermal and hydro-electric power stations, their design and appearance has consistently been unintelligent, while finally, the preparation of such schemes in secret and their issue by instalments amounts almost to a deliberate misleading of the public.

Among the articles included in this number is a severe but reasoned criticism of the Central Electricity Board by Mr. Hugh Quigley which shows convincingly the dangers as well as the opportunities inherent in its structure and its lamentable failure to insist on a national approach, to foster research and development and to elaborate a national plan to which all other interests must be subservient. Those by Lord Forrester on "Industry and its Environment", by Dr. E. F. Armstrong on "Electrochemistry and Metallurgy", by Dr. R. Gilmour on "Electrotechnical Industry and the Highlands", by the late Prof. F. C. Bailey on "Small Hydro-electric Stations", by Prof. C. H. J. Daysh on "Siting of Industry—The Regional Approach", by J. A. Dempster on "The Design of Industrial Buildings" and by G. A. Jellicoe on "Power Stations in the Landscape" and the anonymous article on "The Load Factor" are of most interest to scientific workers as such, but the whole number is a sombre indictment of the present position and of Government negligence, as well as of the Central Electricity Board or the Electricity Commissioners, which is the more impressive because of the restraint with which the evidence is presented.

Atomic Particles from the Sun

OBSERVATIONS during the solar cycle just completed have shown that a close correlation exists between solar flares—transitory patches of enhanced emission visible in hydrogen and calcium light near spots on the solar disk—and terrestrial magnetic storms. Great magnetic storms and auroral displays tend to occur about a day after the appearance of a brilliant flare, and it has been suggested that they are due to charged particles emitted from the sun simultaneously with the visible radiation. If the geometrical conditions are suitable, it is suggested, these particles begin to reach the earth 20–26 hours later, and cause disturbances of the magnetic traces which may last for a day or more. Nearly twenty years ago, Milne gave theoretical reasons for believing that atomic particles might be ejected from the sun at a speed of about 1,600 km/sec, which corresponds to a time of travel of 26 hours. Soon afterwards, Chapman suggested that a comparison should be made between solar spectra at times of magnetic quiet and of magnetic disturbance. The annual survey of the year's work at Mt. Wilson (Adams, *Pub. Ast. Soc. Pacif.*, 56, 213, 1944) now states that solar spectrograms taken in the ultra-violet region during magnetic storms give some indication of two very shallow absorption bands beginning near the centre of the lines H and K and extending about 12 Å towards shorter wave-lengths. Their maximum depth is only 1 per cent of the background continuum. Maximum velocities of the order of 1,000 km/sec and mean velocities of about 600 km/sec are indicated. Control spectrograms taken during magnetic calm show no such absorption. This is the first direct observational evidence of the presence in interplanetary space of calcium ions approaching the earth from the sun at speeds comparable with those predicted both theoretically and by inference from geophysical observations.

Phenomenology and Physics

AN article under this title by H. Margenau appears in the current issue of *Philosophy and Phenomenological Research*. It sets out to expound to the student of physics the main concepts of Husserl and his school, in addition, some consideration is given to the point of view which a physicist interested in methodology might take about the doctrines of phenomenology. At the outset the author is at pains to stress the special meaning attached to the word 'phenomenology'. Far from representing something superficial (that is, associated with 'mere' phenomena) this discipline is the most all-embracing matrix in which, so to say, all experience can be embedded. The paper is in three sections: (1) general thesis of phenomenology, (2) epistemology of physics, (3) the notion of certainty in phenomenology. It seems likely that, of the two types of facts recognized by Husserl, contingent and necessary, the latter are being gradually worn down by a process of attrition as scientific knowledge progresses. Thus a natural question to ask is whether or not the tendency will stop before all *eidetic* (that is, form-like) truth has become contingent. To Husserl, for example, Euclidean geometry appeared "immediately evident and therefore indubitably correct". Here indeed is an example of the rapid strides made by modern science since his day towards contingency. The caution towards ontological problems which phenomenology is forced to observe wrung from Husserl his famous 'epoché' or abstinence, sometimes called bracketing. It implies, even if it does not absolutely require, the waiving of all existential judgments.

With this in mind, we are led to distinguish sense data from 'constructs', and to consider the rules of correspondence relating them. The inadequacy of ordinary language is the cause of much difficulty in making the necessary distinction between percept and correlate. Hallucinations cannot be dismissed too easily, for they are part of the 'given' in nature, but their spurious character is apparent by reference to constructs. Broadly, science is conceived as self-corrective, a property in which phenomenology is lacking. So long as the latter subject is without a discriminant between the infinite variety of forms which inner experience can take, it is likely to remain somewhat unproductive. It seems doubtful whether this disadvantage can be overcome without doing violence, to some part at least, of Husserl's thought.

Swiss Contributions to Western Civilization

UNDER the title "The Swiss Contribution to Western Civilization", Dr. Raphael E. C. Armattee has set forth an account of the cultural achievements of Switzerland which, as Dr. Julian Huxley suggests in his foreword, most people may well find surprising (Dundalk W. Tempest Dundalgan Press. Pp. 91 5s). As the record shows, Switzerland has sent out many from its free institutions to play their part elsewhere, while its universities have attracted many notable men from abroad. It has provided asylum for a number of distinguished workers anxious to avoid tyranny or persecution in their own countries and Switzerland was almost the only centre of science, learning and culture in Europe which was able to remain out of the War. Its part in the reconstruction of European civilization may well be out of all proportion to its size. Dr. Armattee seeks to distinguish from the outset a few sources of the Swiss contribution, but he makes no claim to be comprehensive

especially in dealing with music and the physical sciences. Chemists will note, for example, that while DDT is mentioned, there is no reference to Engi's work, and the reference to the work of P. Karrer and L. Ruzicka is very brief. Besides the sections dealing with the Swiss contribution to biological sciences, the mathematical and physical sciences, agriculture, research in climatology and meteorology, and such special fields as climatic treatment of lung complaints, and Jungfrau-Joch Alpine research, with its humanitarian contributions, there are notes on the Swiss educational system, vocational and industrial education, industry and commerce, Swiss cultural life and so forth.

Public Health and the Museum

IN 1942, authorities of the South Australian Museum, at the request of the Council for Scientific and Industrial Research, examined the River Murray billabongs and seepage areas for Mollusca which might act as secondary hosts for the trematode worm parasites known to be present in the internees of the Loveday Internment Camps. Crustacea and edible fish—together with Cephalopoda taken from the stomachs of the latter—were also examined. The result of this work was a report strongly recommending that the internees should not be allowed in the vicinity of the river, since there was danger of their excreta infecting local fauna, with the possible consequence that the parasites would be introduced into the Australian population (see Report of the South Australian Museum, Adelaide, for 1942). The report for 1944 shows further work of high social value and importance. During last year the research activities of the Museum were turned towards the microscopic study of insects, the Acarina, (particularly the Trombiculinae), which are associated with the occurrence of scrub typhus in Australia and New Guinea. This work was carried out in collaboration with the Medical Section of the Australian Army, the Scrub Typhus Commission of the U.S.A., as well as with officers of the U.S. Navy. It has resulted in making the South Australian Museum the recognized centre for the identification of these mites; and the Museum's collection of these is now probably the largest in existence.

Consider the Calendar

BHOLA D. PANTH has produced a book with the above title, published by the Bureau of Publications, Teachers College, Columbia University, 1944 (pp. 138), which supplies an excellent account of the calendar, and also shows the great difficulties that beset the path of those who desire calendar reform. Details concerning the basic concepts of ancient calendars among the Babylonians, Egyptians, Hebrews, Mohammedans and others will prove helpful to many, more especially as such information is no longer supplied in every issue of the *Nautical Almanac*. Chapter 4 is devoted to a consideration of various proposals for calendar improvement. Reference to some of these proposals has been made in *Nature* (153, 229, 1944), and it is unnecessary to deal further with the different suggestions made to simplify our calendar. The Special Committee of Enquiry into the Reform of the Calendar of the League of Nations in 1926, in Geneva, received 185 plans from 33 different countries, and although this was evidence of keen interest in the subject, it also showed that a certain amount of opposition is inevitable whatever plan be adopted. It does

not seem highly probable that the nations of the world are yet prepared to accept any particular scheme, though some reform on the lines indicated in this book would certainly simplify matters in many ways. At the end of the book there is a short table which enables the reader to determine the day of the week by the Julian Calendar, A.D. 1-2099, or by the Gregorian Calendar, A.D. 1582-2099.

Lung Cavities in Pulmonary Tuberculosis

DR ALFONSO R. SIMS contributes a paper on the spontaneous healing of cavities in tuberculosis of the lungs to *Aparato Respiratorio y Tuberculosis*, No. 3, 1944, published in Santiago De Chile, in which he gives the results of investigations carried out during the period 1937-42 at the Laenec Sanatorium, when 1,130 cases were dealt with. Males only were admitted—adolescents and adults—and it was found that spontaneous cures amounted to only 8.71 per cent. The importance of the size of the cavity was recognized and cures were not effected in cases where the diameter of the cavity exceeded 4-5 cm. It is remarkable that cavities in the left lung showed a greater tendency to heal spontaneously than those in the right lung. Schminke's classification of the cavities as primary, secondary and tertiary, the first having three and the second two subdivisions, was adopted, and it was found that by far the greatest number of spontaneous cures took place with the first class. Infra-clavicle cavities provided the greatest percentage of spontaneous cures, and those at the apex seldom provided any. It is pointed out that great care is necessary before taking any risks in the treatment of pulmonary tuberculosis, and in all cases the patients should be dealt with while they are confined to bed, or at least under the best possible conditions of repose.

Influenza Epidemics in the United States

ACCORDING to Selwyn D. Collins, head statistician of the United States Public Health Service (*Public Health Rep.*, 59, 1483, 1944), in the eighteen major or minor epidemics of influenza that have occurred in the United States since the beginning of 1918, there has been great variability in the age curve. In the recent outbreak, the curve was in general similar to that of 1928-29 except for a very high incidence among children less than ten years of age. Pneumonic incidence in the current epidemic was far below that of 1918-19. Among persons less than twenty-five years of age the pneumonic rate was less in the current epidemic than in any of the others, but above twenty-five the rates corresponded closely to those recorded for the epidemic of 1928-29. The percentage of the total cases which were complicated by pneumonia in the 1943-44 epidemic was far below the figure for any other epidemic for which figures were available. In most of the epidemics the rates for influenza were consistently higher for females than for males, particularly adult females, with the exception of the 1918-19 epidemic and the minor outbreak of 1940-41, in which there were no obvious sex differences.

Cooper Centenary Fellowships for Veterinary Parasitology

THE Veterinary Educational Trust announces that Cooper Centenary Fellowships have been awarded to Mr J. F. A. Sprent and Mr J. Hobart. The Fellowships were established with the Trust by Messrs Cooper McDougall and Robertson to assist in the

development of veterinary parasitology, and also as a mark of the centenary of that Company. They are normally tenable for one, two or three years, depending upon satisfactory progress in the research undertaken. Mr Sprent qualified as a veterinary surgeon at the Royal Veterinary College in 1939 and took a B.Sc. degree in zoology with first-class honours at Birkbeck College in 1942. Since then he has been a veterinary research officer in the Colonial Veterinary Service, stationed at Vom, Nigeria, where he has carried out important investigations upon helminth infestation of cattle in that country. He hopes to continue to work upon helminth infestations of domestic animals with particular reference to host resistance and the development of a host immunity. Mr Hobart took a B.Sc. degree in zoology with first-class honours in 1943 at University College, London. He has been a demonstrator in zoology at the University College of North Wales, Bangor, and has carried out research upon the ecology of adult sheep blowflies in North Wales. His field work has comprised the trapping of flies in the field and the study of the Dipterous succession in small carcasses. This work was commenced in collaboration with the Entomological Unit of the Agricultural Research Council. Mr Hobart proposes to continue his field work in North Wales and to work upon the physiology of insects at the London School of Hygiene and Tropical Medicine.

Comets

A TELEGRAM from Dr Harlow Shapley announces the rediscovery of Comet Pons Winnecke on May 3, its magnitude being 14. A definitive orbit for this comet was computed by Mr J. G. Porter and members of the Computing Section of the British Astronomical Association; and an ephemeris is given in the "Handbook" for 1945. The correction to the computed perihelion is +2.6 days, and the result must be considered very satisfactory as the comet passes just over 0.6 unit from Jupiter, suffering considerable perturbations. Dr Shapley has also announced the rediscovery of Comet Kopff on May 7d 9h 10m UT, its magnitude being 13. An orbit and ephemeris were computed by Messrs W. E. Beart and W. P. Henderson and are given in the "Handbook" of the British Astronomical Association for 1945. A correction of about -8 m in R.A. to the ephemeris is indicated from the observation.

Announcements

THE Catherine Wolfe Bruce Medal (commonly called the Bruce Medal) for 1945 of the Astronomical Society of the Pacific has been awarded to Prof E. A. Milne Rouse Ball professor of mathematics in the University of Oxford, for "distinguished services to astronomy". The medal is awarded on the recommendation of the directors of six observatories, of which two are in Europe. Previous British holders of this Medal have been Gill, Huggins, Dyson, Eddington, Turner, A. Fowler and J. S. Plaskett.

PROF N. R. DHAR, formerly professor of chemistry in the University of Allahabad, has given the University of Calcutta an endowment of approximately one lakh of rupees (about £7,500) for "perpetuating the memory of Acharya Sir Prafulla Chandra Ray and in furtherance of establishing a University College of Agriculture". Prof Dhar states that he hopes to make a further donation of similar amount at a later date.

Striated Structure of Age-hardened Alloys

It is well known that age-hardening of alloys is related to a transformation of the crystal lattice, which takes place inside the crystal; this transformation precedes and prepares the formation of a precipitate from the over-saturated solid solution. The microscopical examination of the crystal surface in the earlier stages of age-hardening shows the existence of one or several systems of parallel striations (see refs 1, 2 for aluminium-copper alloys (per cent Cu), refs 3, 4 for copper-beryllium alloys (2 per cent Be), ref 5 for aluminium-zinc alloys, etc). These striations appear on the sample surface after polishing and convenient etching (see striation), but they may also appear in another way. If the quenched sample is first polished, then age-hardened, the metal surface becomes spontaneously striated. In the case of copper-beryllium alloys, for example, the depth of the striations is very noticeable

(a) Copper-beryllium, aged 4 hr at 315°, after electrolytic polishing
(b) Direction of crystallographic planes, determined by X-ray pattern

What is the origin of these striations which follow age-hardening? Opinions are widely divergent. According to some, they are the trace of glide planes on the sample surface, gliding being due to mechanical stresses produced by the lattice transformations accompanying the age-hardening. On the other hand, Wassermann⁶ attributed the striated structure not to glide-planes, but to mechanical twinning resulting in quenching stresses. A third explanation which has been proposed is the following: the striations are due to the presence of a very fine-grained precipitate, the size of the crystallites being below the resolving power of the best microscopes. The formation of lines of determined orientation are due to the teardrop-shaped form of the initial grains of precipitate, which has been demonstrated by X-ray scattering terms. But this explanation is not consistent with the spontaneous appearance of striations on an alloy surface polished before age-hardening and not etched. A way of deciding between these hypotheses seemed to us to be the determination of the orientation of the striation in relation to the crystal axes. Then, if the striations are due to gliding, they must be parallel to (111) planes (in the case of aluminium and copper alloys), but if they are due to some precipita-

tion, it might be expected that they would be parallel to (100) planes, since the crystals of the precipitate are flat and directed along those planes^{1,3}.

We have carried out this experiment with very coarse-grained samples, in the case of copper-beryllium and aluminium-copper alloys. The crystal axes were determined by back-reflexion Laue patterns. We found that all observed striation systems are parallel to the intersection of some (110) planes with the examined surface. But each (110) plane does not give rise to a striation system. Thus the striated structure of age-hardened alloys is neither related to ordinary glide-planes nor to precipitation planes.

The following explanation accounts for our observations. In the two alloys examined, the solid solution transformation begins by the gathering of the solvated atoms in small areas of some (100) planes. Further, the local enrichment in foreign atoms of these planes produces variations of the interplanar (100) spacings. In the case of copper-beryllium alloy, for example, the parameter of the cell decreases from 3.6 Å (solid solution lattice) to 2.7 Å (precipitate lattice). Then the domain where the beryllium atoms are gathered undergoes a great diminution of volume, which produces the observed depressions upon the metal surface. We may assume that the dislocations between beryllium-rich domains and undisturbed crystal regions take place along (110) planes for these planes are normal to base planes of the precipitate and are very important both in the solid solution and precipitate crystals. The result is that the striations, which are the limits between depressions of different value, are parallel to (110) planes.

In the case of aluminium-copper alloys, the difference between the volume of solid solution and precipitate is much less than for copper-beryllium alloys, and it is observed, in fact, that the striations are much less pronounced.

Structure of Adenosine Di- and Tri-Phosphate

DEFINITE proof of the constitution of adenosine diphosphate and adenosine triphosphate, desirable because of its significance both for the structure of the co-dehydrogenases and of the intrinsic interest of the adenosine polyphosphates, has not hitherto been presented. The usual formulation of adenosine triphosphate as adenosine 5'-triphosphate (I) (Lohmann¹) is in doubt only as regards the mode of attachment of the labile phosphoryl groups to the 5'-phosphoribofuranoside residue, the formation of muscle adenylic acid (adenosine 5'-phosphate) on hydrolysis of adenosine triphosphate and of inosine triphosphate by deamination virtually excludes the location of these phosphoryl groups elsewhere in the molecule.

Structure (I) finds strong support in the careful work of Lohmann¹ on the alkaline titration of adenosine di- and tri-phosphate, he found that the latter contains three primary and one secondary, and the former two primary and one secondary acidic groupings. Other workers (Sato², Barrenscheen and Jachimowicz³) have, however, claimed that it is possible using certain enzyme preparations to remove the acid-stable (5') phosphate residue from adenosine triphosphate, leaving the acid-labile residues intact. This claim is incompatible with the Lohmann formula and, if substantiated, would indicate that the acid-labile phosphate groupings are attached to a second hydroxyl of the ribofuranoside as, for example, in (II).

A decision between (I) and alternatives of type (II) is clearly possible given a test capable of detecting unambiguously the presence of an α -glycol grouping, the Klimek-Parnas test⁴ (formation of a deep blue copper complex) and the Boeseken boric acid reaction were both found positive for adenosine triphosphate⁴, but while this supports structure (I), the tests are not considered decisive in view of the complexity of the molecule. We have recently shown⁵ that the structure of certain nucleosides and nucleotides can be determined by titration with sodium metaperiodate in the manner described for the simpler O-glycosides by Jackson and Hudson⁶, thus adenosine and muscle adenylic acid each containing one α -glycol grouping were found to consume 1 mol metaperiodate, while yeast adenylic acid (adenosine 3'-phosphate), in which one of the α -glycolic hydroxyls is esterified with phosphoric acid, was unaffected by this reagent. We have now extended the method to the study of adenosine triphosphate and find that this substance consumes, almost exactly 1 mol metaperiodate. Details of the experimental procedure follow.

Barium⁷ adenosine triphosphate prepared from rabbit muscle by the method of Barrenscheen and Filz⁷, and purified according to Kerr⁸ until the P/N ratio was constant, was washed with absolute alcohol and dried *in vacuo* at room temperature over calcium chloride. The purity of this material was shown by determination of the atomic ratio acid-labile P/total P/N = 1.99/3.00/5.00, the theoretical value is 2/3/5. Inorganic phosphate present was less than 1 per cent of the total phosphate. Phosphorus determinations

were carried out colorimetrically by the method Allen⁹, nitrogen by micro-Kjeldahl.

451.6 mgm of this material was dissolved in a mixture of 2 c.c. water and 2 c.c. *N* hydrochloric acid, 5 c.c. water containing 0.65 gm $\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$ added, and after 5 minutes the solution was neutralized (*pH* 6.8–7.2) with 2 c.c. *N* caustic soda. Barium sulphate was centrifuged off, washed with water, and the supernatant liquid and washings combined and made up to 50 c.c. with water. Aliquots of the solution were assayed (in duplicate) for phosphorus and nitrogen with the following results: Inorganic P, < 1 per cent of total, acid-labile P, 0.4 mgm/c.c., total P, 0.938 mgm/c.c., acid-labile P/acid-stable P, 1.99/1, N, 0.744 mgm/c.c. The solution was thus 0.104 (± 3 per cent) *M* in adenosine triphosphate. To the major portion of the solution (40 c.c.) 5 c.c. of 0.2536 *M* sodium metaperiodate in 5 c.c. water were added, and the mixture set as at 19°, aliquots being removed at suitable intervals for estimation of unchanged periodate by titration with *N*/10 sodium arsenite. After 48 hours no further uptake of oxidant took place, 0.440 millimol had been consumed, corresponding to 1.06 mol per mol adenosine triphosphate.

We regard the consumption of 1 molar proportion of sodium metaperiodate by adenosine triphosphate under these conditions as conclusive proof of presence in the latter of an unsubstituted α -glycol grouping, that is, structure (I) ascribed to adenosine triphosphate by Lohmann, and the corresponding 5'-pyrophosphate formula for adenosine diphosphate correctly represent these substances. Since, according to Vestin *et al.*¹⁰ an adenosine diphosphate residue forms part of the coenzyme molecule, the results of our present work support the usually accepted formula of this substance. Experiments to test metaperiodate consumption of coenzyme and the related triphosphopyridine nucleotide are at present in progress.

We are indebted to Dr L. P. Kendal, of the University of Manchester, for advice and assistance in connexion with the preparation of barium adenosine triphosphate.

Lecithin and Venom Haemolysis

It is well known that different species erythrocytes exhibit wide variations in their susceptibility to venom haemolysis. Some, such as those of the sheep, the goat and the ox, are totally resistant, while others, like those of the guinea and the dog, are very susceptible. Venoms also vary greatly in their haemolytic activity. Those obtained from the Colubridae class are haemolytic in varying degrees, while the Viperidae species of snakes and venoms which are mostly non-haemolytic. In

resence of a trace of lecithin, however, all species of erythrocytes susceptible or refractory lyse very readily with all venoms irrespective of their nature.

Since the discovery of this remarkable venom-activating property of lecithin, the mechanism of the direct haemolytic action of a native venom upon a susceptible species of red blood corpuscle has been supposed to be the same as that of its indirect haemolytic action in the presence of extracellular lecithin, the lecithin in the former case being assumed to be supplied by the corpuscles concerned (Kyes and Sachs¹). The difference in the susceptibility of various species of erythrocytes, however, was supposed to depend not on their respective total lecithin contents but on the extent to which this intracellular lecithin was free or available for venom activation.

As to the nature and mode of formation of this haemolysin, Kyes² believed it to be a synthetic product resulting from a combination of a venom and a lecithin quota (lecithid), while Coca³ and others regarded it simply as one of the split products of lecithin, namely, desoleolecithin, or lecithin from which one molecule of fatty acid has been removed by the enzymatic action of the venom lipase.

Roy and Chopra⁴, and again Roy⁵, from a comparative study of some of the biochemical properties of venoms obtained from the cobra and the Russell's viper, as representing the Colubridae and the Viperidae, found that the former contained both an esterase (butyric) and a lecithinase, but the latter contained a lecithinase but no esterase. The esterase activity of cobra venom, however, does not run parallel to its haemolytic activity, as it is lost by heating the venom solution to 56°C for half an hour, the haemolytic activity remaining almost unimpaired by this treatment. But if the lecithinase activity of a venom is regarded as the criterion for determining its haemolytic behaviour, as has been assumed even by some recent workers (Huges⁶), then we are unable to explain why the Russell's viper venom, which contains a fairly strong lecithinase capable of forming a very active haemolysin with lecithin, should be non-haemolytic even towards the susceptible species of red blood corpuscle.

The presence of free or 'available' lecithin in the large majority of the species of erythrocytes, therefore, seems to be highly improbable, and the mechanism of the direct haemolytic action of a native venom seems to bear no relation to its lecithinase content, and it is entirely different from that of its indirect activation in the presence of extracellular lecithin. Since the venoms obtained from all species of snakes contain lecithinase A (Contardi and Ercohl)⁷ which splits up lecithin only in a particular manner, namely, into a molecule of oleic acid and desoleolecithin (lysolecithin), and since the latter is capable of dissolving even the most resistant species of red blood corpuscle, their universal lytic action on these corpuscles in the presence of lecithin is self-evident. Another point of difference between the action of native venom and that of the lysolecithin it forms is the presence of lecithin is, that while the former does not lyse an emulsion of cholesterol, the latter dissolves it freely. The formation of lysolecithin is also attended with a remarkable lowering in the surface tension of the solution. It appears probable that with lysolecithin the process of haemolysis is initiated by solution of the corpuscular membrane cholesterol, and when the corpuscular structure is thus somewhat loosened, the sudden change in the surface tension of the solution effects a rapid separation of the

stroma-haemoglobin union. There is reason to believe (to be reported later on) that bile salt haemolysis is brought about in a similar manner.

As the cholesterol solvents are usually those which also materially lower surface tension, it may be stated as a general proposition that substances which dissolve cholesterol will haemolyse all species of red blood corpuscle, though the converse is not true. This, however, leaves the mode of the direct haemolytic action of a native venom still unexplained.

A detailed account of the work will be published elsewhere.

Aliphatic Acids, Fungi and *Mycobacterium tuberculosis*

THERE is no doubt that long-chain aliphatic acids are intimately connected with the metabolism of *Mycobacterium tuberculosis*. Anderson¹ has isolated a number of such acids, including a long-chain hydroxy-acid, from the fatty envelope of this organism. Adams² has shown that acids of the type $RR'CH\text{COOH}$ (containing 16-18 carbon atoms) are, to a certain extent, bactericidal towards *M. tuberculosis*, and Robinson³ has synthesized acids of the type $R''R'''C(CH_3)CH_2\text{COOH}$ (containing 16-18 carbon atoms) which also showed bactericidal activity against this same organism.

So long ago as 1910, Vaudremér⁴ observed that tubercle bacilli were modified by maceration in extracts made from *Aspergillus fumigatus* and *Penicillium glaucum*. A filtrate from a medium on which *Aspergillus fumigatus* had been grown has been found by Soltys⁵ to have an antibiotic action towards *M. tuberculosis*, a similar observation with regard to an *Aspergillus* strain has recently been made by Kallós⁶. Extracts obtained from the culture media of *Penicillium notatum* have been shown by Smith and Emmart⁷ to exhibit "in vitro" marked activity at certain concentrations, and Miller and Rekate⁸ have observed an inhibition of growth of tubercle bacilli by suspensions of a mould which probably belonged to the genus *Penicillium*. It is thus clear that the metabolic products of certain species of *Penicillium* and *Aspergillus* are antibacterial towards *M. tuberculosis*, and it may be noteworthy (see below) that fungi belonging to these genera are well known for their ability to produce citric acid.

Agaric acid—obtained from a Basidiomycete, *Polyporus officinalis*, Vill.—has been employed for many years in the treatment of night-sweats of phthisis. That a fungus-product should have been used for the alleviation of a condition due to *M. tuberculosis* is a curious coincidence, and more especially so, since agaric acid is known to be a long-chain homologue of citric acid (*n*-hexadecyl-citric acid^{9,10}). Agaric acid is, however, said to act pharmacologically as an anhydrotic.

The production of bacteriostatic substances by the larger Basidiomycetes has been investigated¹¹ by Wilkins and Harris, who state that their "results indicate that the larger Basidiomycetes are among the more promising fungus groups which produce antibiotics." These authors, however, base their opinion on the results of tests made mainly on *B. coli* and *Staph. aureus*.

There is a certain structural relationship between agaric acid and those synthetic acids which have been shown to be active against *M. tuberculosis*

Total number of C atoms in molecule

(Adams)	(Robinson)	Agaric acid
16-18	16-18	22

The coincidences are too many to be overlooked, and in my opinion warrant (a) a determination of the antibacterial activity of agaric acid towards *M. tuberculosis*, and (b) an investigation of the synthesis and chemotherapy of related compounds. Both aspects of this investigation are in progress.

Acid Salts of Organic Acids as pH-Standards

MANY monobasic organic acids form crystalline acid sodium or potassium salts (for example, potassium hydrogen benzoate, $\text{KC}_7\text{H}_5\text{O}_2 \cdot \text{H}_2\text{C}_7\text{H}_5\text{O}_2$). A solution of such a compound is equivalent to one of the acid half neutralized with a strong base, and it constitutes a buffer solution that is very readily prepared and that has a pH-value approximately equal to, but slightly lower than, $pK (= -\log K)$ for the acid. Their general usefulness is limited by the low solubilities of most organic acids, and by the comparatively restricted range of dissociation constants among acids otherwise suitable.

Preliminary measurements at 26° show that $M/50$ potassium hydrogen benzoate has $pH = 4.15$ and $M/30$ potassium hydrogen phenylacetate $pH = 4.23$, the pH values being on the scale recommended by Hitchcock and Taylor¹. These solutions are suggested as possible pH-standards, and they are being further investigated from this point of view, together with other similar systems.

Potassium hydrogen phthalate has long been recognized as a pH-standard, but this compound is not strictly analogous to those now suggested. Phthalic acid is dibasic, the buffering capacity of

phthalic acid-caustic potash mixtures is actually at a minimum for the composition corresponding to $\text{KHC}_8\text{H}_4\text{O}_4$, and there is appreciable buffering only because pK_1 and pK_2 differ by not more than $2\frac{1}{2}$ units. On the other hand, borax, which in solution is stoichiometrically equivalent to $\text{NaBO}_2 \cdot \text{HBO}_2$, gives a true buffer solution, and is an acid salt of the type discussed above.

Molar Polarization and Radius-Ratio of Ions

THE interionic distance in the crystalline state is not exactly additive for the radii of the constituent ions. Fajans¹ explains it in terms of polarization. Pauling², on the other hand, neglecting the effect of polarization, explains these deviations from additivity as the effect of the radius-ratio, ρ , of the constituent cation to anion. In this communication a set of empirical equations concerning molar volumes and molar refractions of alkali halides will be first presented. Making use of these empirical equations, we are able to assign definite values to polarization and obtain a function of ρ which, though different in form from Pauling's function, $F(\rho)$, gives identical values.

Fig 1

In plotting the molar volume³, $(V_{MX})_C$, for halide of each alkali in the crystalline state against the volume of halide ions in solution of infinite dilution $(V_X)_S$ ^{4,5}, as shown in Fig 1, a set of straight lines obtained which can be expressed by the general equation

$$(V_{MX})_C = a_1 + b_1 (V_X)_S,$$

where a_1 and b_1 are characteristic constants for each cation.

I have previously shown⁶ that the volume, $(V)_S$, of ions in infinitely dilute solution is a linear function of the volume, V , calculated from Pauling's radii. Therefore $(V_{MX})_C$ bears a linear relation with the volume of anions, V_X .

$$(V_{MX})_C = a_2 + b_2 V_X$$

Taking the volume of ions in solution of infinite dilution as reference, one may consider a_1 in equation (1) as the volume of cations in crystals under the loosening influence of anions and $b_1(VX)_S$ as the polarized volume of anions

The molar refraction² of alkali halides, $(RMX)_C$, in crystals can be also expressed as a linear function of the refraction of gaseous anions $(RX)_G$

$$(RMX)_C = a_0 + b_0 (RX)_G \quad (3)$$

The graph is similar in shape to Fig 1

Ionic polarization If we subtract from each side equation (1) the molar volume of MX in solution, $(MX)_S$, we get

$$(MX)_S = (VMX)_C - (VMX)_S = [a_1 - (VM)_S] - (1 - b_1)(VX)_S = L - P(VX)_S \quad (4)$$

Similarly for molar refraction,

$$(MX)_S = (RMX)_C - (RMX)_G = [a_0 - (RM)_G] - (1 - b_0)(RX)_G = L' - P'(RX)_G \quad (5)$$

This relation is shown in Fig 2. Equation (4), if extended, will give a similar set of lines

Fig 2

The terms L and L' can be called, following the concepts of Fajans¹, the loosening constants of cations, while P and P' are the polarizing strengths of anions. Fig 2 shows that the polarizing strength increases in the order lithium, sodium, potassium and rubidium. Ionic polarization is the combined result of these two factors, L and P

Function of radius-ratio of ions Starting from equation (2) and making use of the classical equation expressing the interionic distance D in crystals in terms of molar volume V , $D = 0.936V^{1/3}$, one gets

$$D = 0.936(a_2 + 4/3 N\pi b_2 r_X^3)^{1/3},$$

where r represents Pauling's ionic radius. Then Pauling's function of radius-ratio can be expressed in the form

$$F(\rho) = \frac{D}{r_M + r_X} = \frac{0.936(m\rho^3 + n)^{1/3}}{\rho + 1}, \quad (6)$$

where

$$\rho \equiv \frac{r_M}{r_X}, m \equiv \frac{a_2}{r_M^3}, n \equiv \frac{4}{3} N\pi b_2$$

Fig 3, the smooth curve is Pauling's function, $F(\rho)$, and dots represent the values calculated from the new function as shown on the right-hand side of equation (6)

Fig 3

In conclusion, the interionic distance D in crystals is shown to be calculable from an equation, equation (6), derived from the equation of polarization and at the same time related to a function of the radius-ratio. A more detailed presentation will appear in the *Journal of the Chinese Chemical Society* (11, No 2)

Red Shift in the Anagalactic Nebulae

Mr A J Shneiderov, in his letter¹ putting forward an explanation of the 'red shift', appears to have overlooked, in examining the effect of gravitational attraction on the frequency of a photon, the fact that the nebula from which the photon originated would exert a contrary effect on the photon to that exerted by the galaxy. If the nebula were of equal mass to the galaxy, then the two effects would balance and no frequency change result.

To explain the red shift in this way would therefore require the galaxy to be much more massive than the great majority of the spiral nebulae so far examined spectroscopically. I believe this is not in accordance with the latest views on the comparative masses of the galaxy and the spiral nebulae.

Furthermore, Mr Shneiderov's formula for the observed energy of a photon originating 'out of the blue' attributes a lower energy to the photon after it has realized on its initial gravitational potential energy than it had at first. The opposite would appear more reasonable. Were this so, no change in frequency would again be expected in the case of equality of mass of radiator and receiver. If, however, the galaxy were smaller than the great majority of the spiral nebulae, a red shift would be expected.

It may be conceivable that most of the extra-galactic nebulae so far examined spectroscopically are unusually large specimens (except perhaps the nearer ones, some of which show a small 'blue shift') so that this modification of Mr Shneiderov's idea might be slightly more plausible

E L DEACON

Meteorological Section,
C D E S,
Porton, Wilts

¹ *Nature*, 155, 332 (1945).

THERE is a somewhat obvious objection to Mr A J Shneiderov's suggestion¹ regarding the red shift in the light received from distant nebulae

If the frequency of light entering our galaxy is altered by its gravitational field, then it must be presumed that the frequency must also have been altered by the gravitational field of the galaxy in which the light originated, but in an opposite sense, so that the two effects would tend to neutralize each other. Also the shift would vary according to the part of the distant galaxy in which the light originated, which does not appear to be the case.

The choice of explanations of the red shift would appear to lie among the following: (i) An increase in distance with lapse of time (Doppler effect) (ii) An increase in the frequency of the atomic oscillators with lapse of time (iii) A decrease in the velocity of light with lapse of time (iv) A change in the frequency (wave-length) of the light in its passage through space

Our choice is limited by our definitions of length and time, which serve to eliminate two of the four possible explanations, or which impose two conditions which the explanation must satisfy

The first three explanations cover familiar ground, but the fourth is also perhaps deserving of consideration. Recent theory has tended to lay special emphasis on quantum effects, but there would seem to be the possibility that the absorption of light in intergalactic space containing molecules, atoms and electrons might be connected with a slight change of frequency

Breeding of the Harvest Mouse in Captivity

THE harvest mouse, *Microtus minutus*, is easy to keep in captivity, this tiny beast flourishing in a roomy cage as many naturalists have proved. One of mine lived with me for nearly four years and died apparently of senile decay. But it has rarely been bred in confinement, indeed I believe that until quite recently the late Miss Phyllis Kelway's achievement of breeding a litter of harvest mice was unique. I say until 'quite recently' because two females in my possession have just produced a litter each. The first family two thirds grown was out and running about on May 12 and the second litter came out, being but half-grown, on May 15. An accurate count was difficult for the small animals kept running in and out of the straw, hay, etc., in their quarters, but my provisional estimate was three in litter number one

and four in litter number two. This may have to be modified.

This establishment consists of one old male and two old females. These, and eight other harvest mice domiciled in another cage, came to me last year through the kindness of Mr W B Atlee from Roms in Hants. Those in the more crowded cage have not shown any signs of breeding. I attribute the success of those in cage number one to roomy quarters as except for being fed and watered—they are most thirsty little animals—to being left undisturbed. They are fed on grain, occasional apple, bread dipped in milk and nuts. They also eat a considerable amount of green food, that is, grass, etc.

FRANCES PITT

The Albynes, Bridgnorth
May 16

Regional International Universities

THE leading article¹ on Dr Joseph Needham's article on "An International Science Co-operation Service" is opportune. We regret that Prof G W Keeton's book, "The Case for an International University" is at present not available to us, but it is obvious that some such organization must be permanently established. We feel, however, that such a service should embrace activities much wider than the mere distribution and exchange of scientific information.

There should be a committee of the United Nations to deal with educational and scientific matters. One of its terms of reference should be the creation of regional international universities where teachers, research workers, postgraduates (and even undergraduate students) of varying nationalities would work under a common roof. It should select the person and, what is most important, indicate the type of subjects to be studied. Subjects that have a universal application and interest should have prior consideration, for example, science, history, law, economic preventive medicine, likewise, any new problem that appears to have international implications should be included.

Such international universities could supplement existing national universities, but should in no way interfere with their autonomy.

Kinematical Relativity and the Nebular Red-Shift

PROF MILNE¹ has not met my objection. I have read his mathematics, and it does not explain a real, objective effect (the red-shift) can be "due to recession" which, according to kinematical relativity is a subjective cause which can be transformed away by an act of thought. Prof Milne's claim that an absurdity must be accepted unless one locates a flaw in the argument leading to it seems to me to call for further comment.

HERBERT DINGLE

[We regret there is no space to continue this discussion.—EDITORS]

PHOTOMETRIC RECORD OF THE MODE OF ACTION OF SULPHONAMIDES AND PENICILLIN

by DR. P. BONÉT-MAURY and R. PÉRAULT
Institut Alfred Fournier (Service de Chimiothérapie) and
Institut du Radium, Paris

WE have obtained these records with the 'différentiel bio-photomètre' recently built by Bonét-Maury and Walen¹ in the Radium Institute, Paris, that apparatus automatically records the variations of opacity of six bacterial suspensions. The growth of the micro-organisms is carried out at 37° C, in special 2-ml flasks, mechanically shaken during the whole experiment while exposed to the beam of light.

The growth of *Staphylococcus aureus*, in glucose peptone broth, gives, for increasing inoculates, parallel curves (Fig 1). The standardization of the photometer with bacterial suspension of known

Fig 1 NORMAL GROWTH OF STAPHYLOCOCCUS, WITH DIFFERENT INOCULATES

Fig 2 DAGENAN AND STAPHYLOCOCCUS CONTROL INOCULATE, 10^6 STAPH/CM³

Fig 3 PENICILLIN AND STAPHYLOCOCCUS INOCULATE, 5×10^6 GM/CM³

Fig 4 PENICILLIN AND STAPHYLOCOCCUS INOCULATE 5×10^6 GM/CM³

Fig 5 SULPHONAMIDE (1162 F) AND *B. coli* LOGARITHMIC LAW IN SYNTHETIC MEDIUM

potency enables one to plot these curves on semi-logarithmic paper, parallel straight lines are then obtained showing that the growth of *Staphylococcus* follows indeed a regular logarithmic growth.

With sulphonamides (Dagenan, 1162 F) in the same broth, it is found by the same graphic means that the curves obtained always indicate logarithmic growth, but the higher the concentration of sulphonamide the slower is the rate of growth (Fig 2). With *B. coli* in synthetic medium, without any anti-sulphonamide agent, the same curves are observed (Fig 5). Everything is exactly as if, at each bipartition, the culture treated with sulphonamide was retarded by a given quantity when compared with the test culture, so that the distance between the two curves regularly increases with time. Thus we can explain why the action of sulphonamide appears to be stronger when it acts on a poor inoculate than on a high bacterial concentration.

It seems to us, from those results, that the sulphonamides, for the concentrations usually reached in the organism, do not stop but just delay the proliferation of the pathogenic micro-organism. In summing up, sulphonamides act on the bacterial proliferation like a fall of temperature, by a slackening of the reaction of synthesis.

With penicillin we observe quite different curves. With high concentrations (100 Oxf u/cm³) proliferation stops almost immediately, followed by a slow lysis of the bacteria², these phenomena seem to be practically independent of the initial concentration of germs. The low concentrations of penicillin (0.1–0.008 Oxf u/cm³) produce particularly interesting curves (Figs 3 and 4).

We observe that, even for very low concentrations, penicillin not only stops the bacterial proliferation in a very short time, but also later shows a very powerful lytic action, the lysis even appears to be more pronounced for higher concentrations.

But if we prolong the recording, a new start of the proliferation is regularly observed (post-lytic growth) followed by a second partial lysis, which is finally followed by a second post-lytic growth. The latter does not appear to be normal, because the final bacterial concentration remains always lower than the test concentration. The results were the same for six different penicillins tested (English, American and French) and correspond to more than fifty curves recorded.

These curves explain the difficulties met with in the titration of penicillin by the dilution method, and the abnormal opacities so often observed when the dilutions are tested photometrically, they probably correspond to the post-lytic proliferation phenomenon. The curves recorded seem to be sufficiently regular, so that we may hope to have a new method of titration by which a given quantity of standard penicillin should be connected with each curve.

PROF. BORIS KELLER

By PROF. N. V. TURBIN

THE Soviet Government has awarded the Order of the Red Banner of Labour to Prof. Boris Keller as a mark of appreciation of his many years of scientific and pedagogical work. Keller was one of the first Russian botanists to make an ecologo-physiological study of the vegetation of the Russian steppes, deserts and semi-arid regions. He aimed at obtaining concrete information on the ways and means by which the evolution of plants takes place in Nature and which lead to their adaptation to differing ecological conditions. He also studied these regions with the view of using them for agricultural purposes.

In studying the flora of the semi-arid regions he made use of his own method of 'ecological series' to study plant associations in connexion with their environment, the method is now widely employed for all phytogeographical work. Keller introduced the conception 'semi-arid region' into the science of phytogeography and was guided by the agrarian peculiarities of these regions as well as by natural and historical features. He compiled one of the best classifications of the steppes and was a pioneer in producing a theory of plant communities, one of the most important divisions of the science.

These investigations are recorded in Keller's works "In the Semi-Arid Zone", "Botanico-Geographical Research in the Zaisan district of Semipalatinsk Region", "In the Valleys and Mountains of the Altai", "Flora of the Russian Steppes, Deserts and

Semi-Deserts" (1923) and others which are still used in Russian universities as classic examples of phytogeographical research in Russia.

All of Keller's investigations pursued the same object—the all-round study of the plant and the dynamics of its relations to its environment. His ecologo-physiological researches form the complement of his physiogeographical field work.

His work on the imperviousness of plants to droughts and salification have become well known. He regards halophytes and xerophytes as examples of the ability of plants to adapt themselves to extreme forms of life. Keller revealed the physiological nature of this adaptation in halophytes and xerophytes and produced a picture of the evolution of these ecological forms.

A group of peculiar fleshy halophytes not only thrives in salified soil but also a certain amount of salt in the soil is necessary to enable them to attain full growth and to protect them against unfavourable factors in the environment, this is a confirmation of the theory propounded by Prof. K. A. Timiryazev—to the effect that "plants are capable of converting hostile elements in their environment to their own use".

On the basis of his ecological and geobotanical researches, Keller explained the general laws of the distribution of plants throughout the world and established actual ecological types. To attain this end he has transferred his studies from one branch of botany to another, from classification to anatomy and physiology and back again to classification in order to investigate "the plant as a whole in all its intricate inter-related peculiarities of its structure and the nature of its life".

His direct contact with Nature and ecological physiological experimentation with living plants strengthened his conviction of the changing nature of plants and the connexion of their properties with the natural conditions with which they have come into contact during their evolution.

Keller is a convinced and consistent protagonist of Darwin's theory of evolution, and his own evolutionary views are based on many years of observations made on plants in their natural surroundings and his research in the sphere of ecology.

The Darwinist nature of his approach to the problems of ecology—the plant, its environment and their interrelations—is the most important feature. Keller's ecological and phytogeographical research. This is what we have in mind when we speak of Keller as an important Russian botanist and Darwinist, this is true of his work in the sphere of phytogeography and the ecology of plants, especially his greatest work, "Fundamentals of the Evolution of Plants", which has been written since the War began. In Keller's works the problems of evolution are first raised as ecologo-physiological problems whereby they differ from many other important works on evolution which give the greatest importance to morphological methods.

Keller explains the specific features of the evolution of plants on the basis of the ways in which the plants obtain nourishment and their relations with the environment.

He is of the opinion that the evolution of plants does not depend on casual, isolated mutations but on the selection of those regular changes which first occur in the individual development of the plant as a regular reaction of its adaptive faculties to changes in living conditions and internal relations in the

plant itself, which then bring about a reconstruction of the progeny in the direction indicated. Environment, therefore, is at once a selective and a formative factor, in these circumstances the formation of a species "as a rule embraces simultaneously many, frequently a very large number of individuals, which are then reformed under the influence of a changing environment or when the plant or a whole family, is transferred to a different region"

During recent years Keller has been putting his ideas on the evolution of plants and his conceptions of the fundamental problems of ecology into practice in the Moscow Botanical Gardens of the Academy of Science of the U.S.S.R. which are being built in accordance with his plans

Prof Keller is a member of the Academy of Sciences of the U.S.S.R. and the Lenin Academy of Agriculture, director of the Moscow Botanical Gardens and president of the Turkmen Branch of the Academy of Sciences of the U.S.S.R. He takes an active part in public affairs and is a member of the Central Trade Union Council of the U.S.S.R. and of the Executive Committee of the Moscow Regional Soviet

SOCIAL RELATIONS OF SCIENCE*

THE advent of peace has led to much discussion on the proper place of science in the post-war world. Different currents of opinion range from the extreme view of the need to suppress science on account of the dangers of its application to war, to that which considers that scientific activities need to be greatly increased and co-ordinated in the interests of providing better conditions of life in Great Britain and throughout the world. Not only is there no agreement as to the amount of science needed, but also considerable divergence of opinion on how science should be organized. Some think of science as "a proper occupation for the leisure of an English gentleman", and consider that it is more important that it should be completely free and unorganized than that it should be adequately endowed, while others feel that the full value of science can only be reached if it is organized in relation to practical human activities of production, agriculture and health, and can draw on a far larger share of the national income than it has done hitherto. Those who hold the older views have never realized that the relation of science to society is not fixed but continually changes with the growth of science and the increase of complexity of society. What did well in ancient Greece or Victorian England is not appropriate to the needs of to-day.

Science is not a simple thing, it eludes definition; it is at the same time a professional activity, a body of knowledge, a way of solving problems and an influence on the way in which everyone looks at the world and deals with it. Society is fully entitled to demand that science should be used in solving the problems of providing us with a better standard of living. It would be a very stupid society, however, that attempted to do this without considering the beliefs and ideals of scientific workers and the unity of scientific knowledge, which is such that almost any part of it may turn out to bear on almost any other. The Nazis tried to do this: they discouraged fundamental science and generalized thinking and

thus, in spite of their enormous technical start, failed in war. Men of science who are taking the responsibilities of science seriously are well aware that a proper proportion of effort must be given to fundamental science which has no immediate application. Out of £24 millions, which the Association of Scientific Workers suggests should be budgeted for scientific research in Britain, more than £2 millions would go to fundamental science. The Association is also aware that the actual direction of scientific effort must be in the hands of scientific workers, who alone are competent to know what they are doing.

It is quite possible to plan science, as the example of Britain during the War and the Soviet Union before the War, have shown, in such a way that a continuous link is kept between applied science and fundamental science with a two-way flow of ideas—of new ideas coming from fundamental science to be applied, and of problems coming from the applied field leading to the production of new fundamental theories. The real danger to Great Britain is not that science will be over-organized, but that there will not be nearly enough of organized science. We spend only about one third as much, in proportion, and one tenth in total, as the United States and the Soviet Union on scientific research.

The immediate limiting factor is the number of scientific workers who will be available in the post-war years. With our present educational output, we can never produce scientific workers in adequate numbers, but the importance of this has not been realized, and the additional grants made to the Universities' Grants Committee will scarcely do more than make up for the increased cost of living.

Science is in this situation very largely because its wider influence has never been realized by the public. Science teaching is a belated and unwelcome part of the educational system, and the new Education Bill has not improved matters. Further, the Press generally treats science only as a purveyor of sensational discoveries.

The War, however, has shown millions of people in the Services and the war factories how important science can be. The very demands which are now being made for adequate food, housing and health are known to be based on scientific studies. The new standards can be achieved only by the application of science. Beyond that, we are beginning to see that not only these problems but also many political and social problems depend on science for their solution. With this realization we may hope will come an increasing emphasis on the balanced development of science, on its increasing use in satisfying social needs and on the spread into ordinary life of a scientific way of thinking and acting.

ISLAND FLORA OF THE GULF OF GUINEA

THE three Portuguese islands, S. Tomé, Príncipe and Annobon, which form the subject of this work* lie, together with Fernando Po, in the Gulf of Guinea. All are of comparatively recent volcanic origin and have a typical equatorial climate with considerable rainfall and very high humidity. Geological evidence and the insular character of their

* Catalogue of the Vascular Plants of S. Tomé (with Príncipe and Annobon). By Arthur Wallis Exell, and other members of the Department of Botany. Pp. xi+428. (London: British Museum (Natural History), 1944.) 30s.

* Substance of the Trueman Wood Lecture delivered by Prof. J. D. Searl, F.R.S., before the Royal Society of Arts on May 16.

floras both point to the three islands never having had any land connexions with each other or with the continent. The islands have been visited many times by botanists and their flora is fairly well known, but Mr Exell was able, during a three months visit in 1932-33, to add thirty-one new species, and considers that the mountain forest region in St Thomas and Principe is still by no means exhausted.

The vegetation of St. Thomas, the largest and most diversified of the three islands, is divisible into four regions. The littoral region consists of sand dunes or mangrove swamps. The lower-lying ground up to 800 m, originally occupied by rain forest, is now almost entirely under cultivation. The plantations are mainly devoted to cocoa, coffee, bananas, oil-palms and coco-nut palms. The mountain rain-forest region between 800 m and 1,400 m is remarkable for its richness in Rubiaceae and Euphorbiaceae, and for an equally striking absence of Leguminosae. Epiphytes and lianes are well developed, and the profusion of ferns both as to species and individuals is probably unsurpassed in any other part of Africa. At still higher elevations up to the summit of Mt. Pico (2,024 m), there is developed a mist-forest region, determined by the cool climate, very heavy rainfall and almost constant mist. Here the trees are less lofty and the canopy less dense than in the mountain forest region, and epiphytes and ferns are even more abundant.

In the much smaller island of Principe, what little virgin forest remains seems to resemble that of the lower rain-forest of St Thomas, with Rubiaceae, Euphorbiaceae, Orchidaceae and Filicemae particularly abundant.

The total number of indigenous species on the three islands is 682, of which 171 are endemic, this is a high degree of endemism having regard to the nearness of the continent. Only eleven of these endemic species occur on more than one island and this, together with the fact that each island has a comparatively large number of species found on the mainland but not on the other islands, affords strong evidence that the islands were never connected with each other, but that each received its independent quota from the rich mainland flora.

The information given under each species includes synonymy, distribution within the islands and beyond, and citation of all known specimens in herbaria. Most of the newly described species are figured.

FORTHCOMING EVENTS

Monday, June 11

GAS RESEARCH BOARD (at 1 Grosvenor Place, London, S W 1), at 2 p.m. Annual General Meeting.

ROYAL COLLEGE OF SURGEONS (Lincoln's Inn Fields, London, W C 2), at 4 p.m.—Prof F Davies "The Early Development of the Human Embryo" (Arris and Gale Lecture).

WOMEN'S ENGINEERING SOCIETY, Manchester Branch (at the Engineers' Club, Albert Square, Manchester), at 6.30 p.m.—Miss V Holmes "Women and Workshop Skill".

ROYAL GEOGRAPHICAL SOCIETY (Kensington Gore, London, S W 7), at 8 p.m.—Dr J V Harrison "Journeys in Luristan".

Tuesday, June 12

ROYAL SOCIETY OF ARTS (John Adam Street, Adelphi, London, W C 2), at 1.45 p.m.—Dr F M Walsh, O.B.E. "Infantile Paralysis" (postponed from May 9).

CHEMICAL ENGINEERING GROUP OF THE SOCIETY OF CHEMICAL INDUSTRY and the INSTITUTION OF CHEMICAL ENGINEERS (at the Geological Society, Burlington House, Piccadilly, London, W 1), at 2.30 p.m.—Mr L W Needham and Mr S Lyne "The Use of Suspensions as Heavy Liquids" (postponed from May 8).

QUEKETT MICROSCOPICAL CLUB (at the Royal Society, Burlington House, Piccadilly, London, W 1), at 7.30 p.m.—Mr E Mackie "A Consideration of the Requirements for Cinemicrographic Apparatus".

Wednesday, June 13

INSTITUTE OF PETROLEUM (26 Portland Place, London, W 1), at 5.30 p.m.—Chairman of the Heavy Duty Engine Oils Panel of the Standardization Committee of the Institute "Engine Testing of Heavy Duty Oils".

Thursday, June 14

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W 1) at 4.30 p.m.—Dr G M B Dobson, F.R.S., in collaboration with Mr A W Brewer and Mr B Cwiling "The Meteorology of the Lower Stratosphere" (Bakerian Lecture).

Tuesday, June 12—Wednesday, June 13

INSTITUTION OF GAS ENGINEERS (1, Grosvenor Place, London S W 1) Annual General Meeting.

Friday, June 15—Saturday, June 16

INSTITUTE OF BRITISH FOUNDRYMEN (at the Waldorf Hotel, Aylesbury, London, W C 2)—Annual meeting. Members of the Iron and Steel Institute are also invited to attend.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned.

LECTURER IN MATHEMATICS at Battersea Polytechnic, London S W 11—The Clerk to the Governing Body (June 11).

SENIOR EXECUTIVE OFFICER responsible primarily for Research and Public Relations, Institute of the Motor Trade—General Secretary, marking envelope "Executive Officer" (June 16).

A LECTURER IN MECHANICAL ENGINEERING, and a LECTURER IN ELECTRICAL ENGINEERING, at West Ham Municipal College—The Education Officer, Education Offices, 95 The Grove, Stratford, London E 15 (June 16).

LECTURER IN CHEMISTRY at the Royal Technical College, Salford. The Principal (June 18).

LECTURER IN PHYSICAL AND INORGANIC CHEMISTRY, Royal Holloway College, Englefield Green, Surrey—The Principal (June 18).

TWO TECHNICAL OFFICERS for the Ministry of Food, to supervise factory production of dehydrated food—Ministry of Labour and National Service, Central (T and S) Register, Room 5/17, Sardinia House, Kingsway, London, W C 2, quoting F 3854 A (June 20).

TWO CHEMISTS (Technical Officers) in the Infestation Division the Ministry of Food—Ministry of Labour and National Service, Central (T and S) Register, Room 5/17, Sardinia House, Kingsway, London, W C 2, quoting F 3874 A (June 20).

INSTRUCTOR AND LECTURER ON INDUSTRIAL CHEMISTRY at the National Fire Service College, near Brighton—Ministry of Labour and National Service, Central (T and S) Register, Room 5/17, Sardinia House, Kingsway, London, W C 2, quoting F 4165 A (June 20).

LECTURER IN CHARGE OF THE DEPARTMENT OF ZOOLOGY, University College, Leicester—The Registrar (June 20).

ASSISTANT LECTURER IN PHYSICAL AND INORGANIC CHEMISTRY at Queen Mary College, University of London—Acting Registrar the College, c/o King's College, Cambridge (June 20).

LECTURER IN AGRICULTURE AND FARM MANAGER at Harper Adams Agricultural College, Newport, Shropshire—The Principal (June 20).

LECTURER IN BIOCHEMISTRY for the Yaba School of Medicine, Nigeria—Ministry of Labour and National Service, Central (T and S) Register, Room 5/17, Sardinia Street, London, W C 2, quoting F 4082 A (June 21).

LECTURER IN CIVIL ENGINEERING in the University of Birmingham—The Secretary (June 23).

PRINCIPAL OF NEWTON HEATH TECHNICAL SCHOOL—The Director of Education, Education Offices, Deansgate, Manchester, 3 (June 2).

LECTURER IN BUILDING SCIENCE at the Huddersfield Technical College—The Director of Education (June 25).

PROFESSOR OF PHYSIOLOGY at King's College of Household and Social Science—The Academic Registrar, University of London, Richmond College, Richmond, Surrey (June 26).

CO-ORDINATOR OF RESEARCH AND PRINCIPAL OF THE PUNJ AGRICULTURAL COLLEGE, LYALLPUR—Ministry of Labour and National Service, Central (T and S) Register, Room 5/17, Sardinia Street, London, W C 2, quoting F 4220 A (June 26).

READERSHIP OF ENTOMOLOGY in the University of Durham, tenable at King's College, Newcastle-upon-Tyne—The Registrar of King's College (June 30).

INSTRUCTOR-ORGANIZER FOR MINING EDUCATION under the Shropshire Education Committee—The Secretary for Education, Courthouse Buildings, Shrewsbury (June 30).

LECTURER-IN-CHARGE (female) OF THE HOME SCIENCE DEPARTMENT, Technical Education Branch, Education Department, Sydney Acting Official Secretary, New South Wales Government Offices, 1 Strand, London, W C 2 (June 30).

UNIVERSITY DEMONSTRATOR IN ENGINEERING, University of Cambridge—The Secretary of the Appointments Committee, Engineer Laboratory, Cambridge (July 2).

ASSISTANT EDUCATION OFFICER FOR TECHNICAL EDUCATION to the Hertfordshire County Council—The County Education Officer, Courthouse, Hertford (July 3).

TWO LECTURERS IN THE DEPARTMENT OF PHYSIOLOGY, one with special knowledge of Experimental and Human Physiology, and other with experience in Biochemistry, University of Aberdeen. The Secretary (July 7).

ASSISTANT with special knowledge of PHYSICAL or INORGANIC CHEMISTRY in the Department of Chemistry, University of Aberdeen—The Secretary.

LECTURER IN HYGIENE at Derby Training College for Women Teachers, 93 Uttometer New Road, Derby—The Principal.

LECTURER IN MECHANICAL ENGINEERING, and a LECTURER IN MATHEMATICS OR SCIENCE, at Birkenhead Technical College, Birkenhead, Kent—The Principal.

A SENIOR OFFICIAL OF THE INSTITUTION OF STRUCTURAL ENGINEERS—The Secretary, 11 Upper Belgrave Street, London, S W 1, mark the envelope "Science".

CONTROL OF SCIENCE IN GERMANY

ON two successive days, May 29 and 30, Lord Cherwell was called upon in the House of Lords to reply on behalf of the Government to inquiries dealing with the control of scientific development in Germany, with special reference to applications in warfare. Such inquiries are evidence of the keen interest which is being taken in this topic, and should be welcomed since they made it possible to give authoritative assurances and also dispose of some of the more alarming apprehensions of which we have heard so much in the past few months.

The first inquiry, general in character, came from Lord Vansittart. He said that unless strict control be maintained over scientific developments in Germany, there will inevitably be developed even more potent 'secret' weapons than those from which we suffered in recent months. Provision should also be made to guard against other countries, whether Allied or neutral, granting Germany permission to use devices developed by them which were potentially dangerous. He therefore advocated the control of all German laboratories, university and industrial, through an extensive and intensive intelligence service provided from the United Nations. In addition, Lord Vansittart suggested the formation of a civil inspectorate, which might in time become a world inspectorate on the watch for the development or over-development of secret devices likely to be turned against mankind. Without some such safeguard, he predicted that nations would quickly become involved in a secret armaments race more terrifying than any previous such race. Lord Vansittart therefore asked the Government to take the initiative in proposing the inclusion in the terms to be imposed on Germany of an article providing for an inter-Allied committee of scientific men to examine and control, and if necessary prohibit, the use by Germany of any scientific invention or discovery considered likely to be dangerous to the safety of mankind.

Lord Strabolgi supported this view, and suggested that similar action should be taken against Japan. Incidentally, he suggested that Lord Vansittart gave the impression that it was the discovery of new weapons which makes wars. This would put the responsibility for war on scientific men and inventors, this, as Lord Strabolgi commented, is incorrect. The worst that can be said of men of science in this connexion is that they are coerced or persuaded or bribed into helping the real war-mongers.

The second inquiry, more specific in character, came from Lord Brabazon, who discussed particularly the so-called directed missiles, the flying bomb and the rocket. The engine of the flying bomb, he said, developed 350 h.p. and cost about £15, while the rocket is capable of immense development—"the physicist's dream or nightmare." He believes that the policing of Germany will be relatively easy for ten years, after which troubles will begin to arise. The technique of rocket propulsion is bound to develop, and he drew a vivid picture of a future power secreting long-range rocket weapons, with new

explosives and new powers of control, and unleashing them swiftly against the great cities of its enemy with terrible effect before armies could be assembled. He therefore suggested the constitution, as a part of the peace organization, of an international committee of inspection with power to enter works anywhere in the world. There are, he said, only two alternatives to push on vigorously, in combination with the United States, the development of this technique in order to obtain a lead over the rest of the world, or to invent such machinery of inspection as may be necessary to prevent development.

The story was taken up by the Earl of Darnley, who painted a gruesome picture of the war of the future, in which the fighters would be bands of troglodytic alchemists dealing out death to millions. He also referred to the atomic bomb, which he said was almost ready at the end of the War. Any future war might last only a few minutes, and might end before survivors knew what had happened. The development of such engines of war would lead to the extermination of the human race. Lord Darnley's address reminded one of H. G. Wells' "War in the Air", revised and with a modern setting.

Lord Cherwell's replies set out the Government's policy and also provided a survey in general terms of the problem of secret weapons and related topics. He said that the Government appointed a committee of scientific men a year ago to consider the whole question of the future of scientific research in Germany, and that a report of its preliminary conclusions will shortly be ready, "the Government," he said, "will certainly give the greatest weight to them." Any proposals, however, must be discussed with our Allies, and a concerted policy agreed upon. A scientific and technical staff has been attached to Supreme Headquarters of the Allied Expeditionary Forces for some time, the duties of which have been the examination and control of German activity in these fields. All German activities, including scientific work, will come under the Control Commission. It would be premature, in the Government's opinion, to make specific proposals for inclusion in any eventual peace treaty. He assured the House, however, that the Government intends to see that scientific men will continue to play their part both in disarming Germany and securing the future against the use of scientific developments by that country for war-like purposes.

In discussing the general problem of secret weapons, Lord Cherwell gave a well-balanced account of the approach from a scientific point of view. The problem is a grave one, as he admitted, but spectacular or unexpected results must not be allowed to outweigh the conclusions of careful investigation. In the first place, Lord Cherwell said that a distinction should be drawn between pure science and its applications, in the former, the Germans are definitely behind the leading Allied nations, in the latter, they have maintained a high reputation, due largely to their methods of training. But the new German weapons of war, while they were well-executed pieces of engineering designed for a particular purpose, did not involve any new scientific principle. Radio-

location is an application of the experimental fact known for the past fifty years, that a metal object scatters electromagnetic waves, and many nations including the Germans, applied themselves to its development as a means of detecting aircraft at night. German engineers produced a workable method, but it was not so efficient as that developed in Great Britain.

Dealing with Lord Vansittart's suggestion for an international scientific committee for the investigation of developments in German laboratories, Lord Cherwell pointed out the difficulty of deciding at what stage a scientific discovery might be considered likely to be potentially dangerous in unscrupulous hands. Thus, in the investigation of electromagnetic radiation, supposing such a committee had been in existence when their existence was predicted by Clerk Maxwell, would it have been able to act immediately? Or would it have deferred action until Hertz detected the radiation a few years later, or when Marconi demonstrated its commercial use, or when broadcasting was in its infancy? Another example quoted by Lord Cherwell to emphasize his contention was the discovery by Elster and Geitel that a negatively-charged plate of zinc loses its charge when ultraviolet light impinges on it. This effect is the basis not only of the talking film, but also of modern instruments for measuring the velocities of shells and bullets. Indeed, it is a truism to say that no one can foresee all the possibilities of a scientific discovery, and Lord Cherwell clearly does not believe that an international committee of investigation would be of much value. Nevertheless, as has been said above, he stated that the Government intends to pay adequate attention to scientific aspects of control.

Lord Cherwell re-affirmed this point in his reply to Lord Brabazon, before passing on to deal specifically with the question of long-range weapons. He pointed out that range is not the only consideration in warfare. The R.A.F. produced a pilotless aircraft some years ago, he said, but development was stopped because it was found that the weapon was not accurate enough to hit the kind of targets which we were likely to be concerned. London is a unique target with about 700 square miles of built-up area and within a hundred miles of a foreign coast-line, and the Germans considered it worthwhile to attempt the kind of random bombardment which the use of such weapons involves. The only guided missile described during the War was the wireless-controlled glider bomb used by the Germans against shipping.

Some interesting figures were given by Lord Cherwell about the cost of production of long-range weapons. He equated one bomber to a hundred 'flying bombs', and bearing in mind that the range of the latter was about 140 miles and its accuracy less than a tenth of that of a bomber, it was clearly an uneconomic weapon. The rocket, V2, is believed to be even more uneconomic, for Lord Cherwell said that it probably cost twenty times the number of man-hours to produce. Granting that the bombardment with flying bombs and rockets caused mu-

suffering, they can only be used against a target area of large dimensions, and the cost of production in man-hours can generally be spent to more effect on the manufacture of bombers. The total weight of the war-heads of flying bombs which crossed the English coast during three months was less than 6,000 tons, and about half of these bombs reached the London area, in seven months of bombardment by rockets, about 1,000 tons of war-heads reached England, and only about a half reached London. Against such figures can be put the facts that the R.A.F. was able to drop nearly 5,000 tons in a single attack, in many cases with half of the bombs within a mile of the target, and that the attack could be launched on any city in Germany.

If, however, the anti-aircraft defences of a country could be developed to the point when it became exceedingly dangerous for bombers to fly over it, then there would be a case for long-range weapons at the very length of range militated against their accuracy. The only means known at present of guiding such missiles to their targets is radio, and very elaborate anti-jamming devices would be essential. Moreover, the greater the distance from the launching point, the greater the efficiency of jamming, half-way along its trajectory, the guiding transmitter and the jamming devices might have equal power, but at three-quarters of the distance or range, the jamming might have a ninefold superiority, and so on.

Lord Cherwell also referred to the possibility of utilizing atomic energy. He stated that there has never been an instance of the experimental disintegration of an atom without a collision of one of the bombarding particles and the nucleus of an atom, and there is no reason to think that the disintegration would extend to ordinary matter, thus bringing about the explosion of the whole earth. Nevertheless, Lord Cherwell said that unless the nations could agree on some form of limitation of weapons, their range and lethality would undoubtedly increase, and we in Great Britain have the most to lose by this. He therefore insisted that, until an international organization can guarantee our safety, we must keep ahead in all scientific and technical advances of warfare, and the Government would spare no effort to do so.

Lord Cherwell's statements will be widely welcomed. They dealt with the question of the 'terror' weapons used by Germany against the background of warfare in general and bombing by piloted aircraft, demonstrating effectively the relative superiority of the latter for large-scale effects. Nevertheless he concluded the possibilities of development, to guard against which intense scientific effort will be necessary. As will apparently take two forms: the strict control of German laboratories, and increased activity on our own. But the first step will be consideration of the report of the scientific committee discussing scientific research in Germany. It is to be hoped that the general conclusions of this committee, if not the whole report, will be made available for discussion, for it will be a document of the greatest interest to scientific workers.

MEDIEVAL ORNITHOLOGY

The Art of Falconry

Being the "*De Arte Venandi cum Avibus*" of Frederick II of Hohenstaufen. Translated and edited by Casey A. Wood and F. Marjorie Fyfe. Pp. 6x+637 (186 plates). (Stanford University, Calif.: Stanford University Press, London: Oxford University Press, 1943.) 60s. net.

IT will scarcely be questioned that this work of the great Roman Emperor, the founder of the University of Naples in 1224, is one of the most remarkable scientific documents which have come down to us from the Middle Ages. Having said this, it is astonishing to have to add that the present edition is the first appearance of the complete work in print in any language. We owe this tardy recognition to the devotion and learning of the senior translator, Dr. Casey Wood, the founder of the Wood Library of Ornithology at the McGill University, Montreal. The fact that there is a widespread revival of interest in Frederick's researches in ornithology is the achievement of another distinguished American scholar—the late Prof. C. H. Haskins. What is needed now is the publication of a standardized Latin text collated from all the known manuscripts, but the task would be long, arduous and costly.

The first printed version of 1596 in Latin is by Marcus Velser and is based on the incomplete Vatican manuscript. It includes only Book 1 and the first thirty chapters of Book 2, and also lacks nine chapters of Book 1. These missing chapters, however, are to be found in the thirteenth-century Bologna manuscript, which is the earliest version of all six books, and was therefore (in conjunction with the Vatican manuscript) employed as the chief source of the present translation. The second Velser edition of 1788–89, by the zoologist J. G. Schneider, is particularly valuable on account of the commentary and notes of its distinguished editor. Both these Latin texts are exceedingly rare, especially the latter. The only other printed editions are two German translations of Velser's text.

It is generally agreed that Frederick is the author of the original work, and he may even have been its scribe and illustrator. It was written after some thirty years of preparation between 1244 and 1250, and it terminates abruptly at Chapter 34 of Book 6. He mentions his intention of writing a section on the diseases of birds, which, if written, has not survived, and as he himself died in 1250 it seems certain that the work was never completed.

The present volume includes an annotated, illustrated English translation of the complete Latin text, based on a comparison of the twelve available manuscripts in European libraries, a chapter by the English zoologist Cresswell Shearer on the castles and hunting lodges of the Emperor, appendixes on various topics of practical and historical importance to falconers, an annotated list of the birds mentioned and figured by Frederick, and an admirable critical bibliography of ancient and modern falconry, together with a glossary and index. The book is lavishly illustrated, and the Stanford University Press has demonstrated that typography of the highest class is still possible in America in war-time.

The Emperor stands out from his contemporaries as an original thinker and observer. The methods of the scholastics, which at that time were coming into dangerous prominence, were rejected, and he saw

that science could advance only by research. Shearer rightly claims that the "De arte venandi" is the "first zoological treatise written in the critical spirit of modern science". Thus, for example, the barnacle goose myth is methodically investigated by Frederick, and dismissed as a superstition based on ignorance of the real nesting places and fledglings of this bird, but none the less the superstition survived until the eighteenth century*. Nor does the Emperor confine his studies to the falcons used in hunting. He is interested in birds generally, and his work must be regarded as the first generalized treatise based on original investigation of the species, habits and structure of birds. His philosophical outlook is that of the teleologist, who interprets adaptations as evidence of an ordered and designed world into which the peculiarities of avian structure must, and can, be fitted in.

The part of Frederick's work relevant to the interests of this journal is Book I, which deals with the biology and anatomy of birds, especially, but by no means entirely, of the species employed in hunting. Particular attention is devoted to external characters, habits of feeding, reproduction, and locomotion in all its forms. A comprehensive account is given of plumage, how and when it is moulted and the different types of feather, with their distribution over the body and their functions in the general economy of the bird. The *ala spuria*, with its four *plumæ pollicis*, is described. He mentions, and evidently saw, a single bone only in the *ala*, but the present translators render this passage in the plural, which is correct as a statement of fact but is not what the Emperor wrote. Frederick's views on the function of this part are fanciful and strange even for his own time.

The Emperor's discussion of his researches on the problems of bird migration is admirable and detailed, although he could not be expected to have deduced or guessed the historical setting of avian migration. He distinguishes several geographical and climatic types of the phenomenon, and he also perceives that the colder of the two climates inhabited by a migratory bird, namely, that in which it nests, must be regarded as its original home. His anatomical notes, if somewhat scanty, include some interesting and acute observations. He describes the nictitating membrane of the eye—previously, however, known to Aristotle—and appears to have seen parts of the osseous labyrinth of the ear. His account and interpretation of the skeleton of the wing is on the whole sound, but his *tour de force* is a comparison of the skeleton of wing and leg. Here, basing his conclusions on the limb skeletons of various birds, he correctly homologizes, and for the first time, the bones of the leg, and avoids the pitfall of regarding the tarso-metatarsus as the shin bone. Other features in the anatomy of birds known to Frederick are the muscles of flight, the distinction between the stomachs of carnivorous and graminivorous birds, the uropygial gland, the sinus rhomboidalis of the spinal cord and ventricles of the brain, the hyobranchial apparatus, the absence of an epiglottis, the aperture of the Eustachian tubes, the absence of the gall bladder in some birds and of the urinary bladder in all, and the fact, known to Aristotle, that the rectum and urogenital ducts open into a common chamber or cloaca. The Emperor also describes the looping of the trachea in the sternum

of the crane, which he associates with the production of the deep call of this bird, and he noted that the pairs of spinal nerves emerged from the backbones between contiguous vertebrae.

We have checked the translation against Velser's printed text only in those cases where the rendering was obviously open to question. Even this, however, could not always be done, owing to imperfections in the Vatican manuscript which was the version transcribed by Velser. The statements that "sterile eggs lack the activating male spermatozoa" and that impulses are carried to all parts of the body by "motor and sensory nerves" scarcely suggest an original written in the thirteenth century. The "vaginae deferentes" are obviously the ureters, and not the uriniferous tubules, which Frederick could not possibly have known. In Chapter 44 the translators imply that the Emperor described a pair of ovaries in birds, whereas he distinguishes between the sexes by using the plural in his account of the male, and the singular in that of the female. It is clear that he was familiar only with the functional left ovary and oviduct present in most birds.

Dr Casey Wood did not live to handle the beautiful volume he had wrought so hard, and for so long, perfect, but the work itself remains as a lasting monument to his memory. F. J. COLE

MEDICINE IN THE TROPICS

Tropical Medicine

By Sir Leonard Rogers and Sir John W. D. Megaw (Churchill's Empire Series). Fifth edition. Pp. x + 518. (London: J. and A. Churchill, 1944.) 21s.

A GOOD indication of the value of this book is the fact that five editions of it have appeared since 1930 and that two editions have been required since the third edition in 1939. Originally the book was written for the general practitioner in the tropics rather than for the specialist with up-to-date laboratory facilities at his disposal. The aim of the author was to provide a small and handy book which would give a broad survey of the field of tropical medicine and yet would deal adequately with the diagnosis and management of diseases commonly encountered in the tropics and subtropics, with such methods of microscopical study and laboratory diagnosis as the general practitioner could carry out by himself. Such a book could only be written satisfactorily by an author with wide experience of the practice of medicine in the tropics who also had the power of communicating their experience to others and the judgment necessary for the wise selection of the essentials.

It would be difficult to find anyone who possesses these qualities in greater degree than do Sir Leonard Rogers and Sir John Megaw. They have produced a volume which is both a general introduction to this fascinating subject and a practical guide of great value. It is likely to have greater value in the future for the wide dissemination of Allied troops in tropical countries during this War carries with it a risk of the spread of tropical diseases both to areas within the tropics and sub-tropics and to non-tropical countries. The control of this risk has already required the creation of a considerable organization, and in the control the general practitioner must play an essential part. As the authors of this book point out, successful treatment of tropical diseases—and indeed of

* In his fascinating book on the barnacle goose, Heron-Allen states that Frederick does not mention the myth, but this is an error traceable to the printed text which lacks the chapter in question.

lises—depends upon early diagnosis, and prevention of them is no less dependent on this. The general practitioner therefore mans the front-line observation post upon which the artillery of preventive medicine relies. He will find in this compact and authoritative volume an invaluable source of the accurate information which he must have.

In this fifth edition no change has been made in the plan and scope of the book, its size has not been increased, it is, in fact, a few pages smaller, but many pages have been entirely rewritten, especially the chapters on malaria, kala-azar, trypanosomiasis, the fevers of the typhus group, leprosy and the dietetic diseases. Although the results of much modern work have been included, the book evidently went to press just too early for the inclusion of any reference to the remarkable success of D D T for the control of the lice which transmit epidemic typhus fever (cf *Nature*, 154, 600, 1944). Possibly much more information than can at present be released about the uses of D D T will be available for a post-war edition in which it will, we may hope, be possible to include so valuable data obtained during the War which is not yet available for general publication. The possible value of penicillin for the treatment of typhus fever and other Rickettsial diseases is mentioned in the addendum on the treatment of louse typhus at the end of the book. Incidentally, the chapter on the febrile diseases caused by Rickettsia bodies is one of the most clearly stated short accounts that we possess of the essential differences between epidemic and endemic, louse-borne typhus (including Brill's disease) on one hand and, on the other, the non-epidemic, zootic typhus fevers (murine endemic sea-borne typhus, tick-borne Rocky Mountain spotted fever, the mite-borne Japanese river fever which is also called tsutsugamushi or scrub-typhus and the other types of tick-borne and mite-borne fevers which resemble typhus).

The section on dietetic diseases is introduced by a chapter on dietetic errors in the tropics which should be read by all who contemplate going there. These chapters on the dietetic diseases and the chapter on the effects of such climatic factors as sunlight and heat, with the wise advice given on the methods of combating the tropical climate by means of clothing, modern methods of cooling and so on, should enable visitors to the tropics to avoid lowering their resistance to tropical disease or becoming victims of the direct action of climatic factors themselves. Only those who have lived in the tropics can appreciate the importance of this kind of personal and general hygiene. Another valuable chapter, by Sir Leonard Rogers, compares the incidence in Calcutta and London of general diseases which are encountered all over the world, so that the reader can form an idea of what he is to expect apart from tropical diseases themselves. The importance in the tropics of these non-tropical diseases is often underestimated. The extreme importance of the problem of tuberculosis in India, for example, has been only recently realized. Sir John Megaw adds a section which amplifies the conclusions drawn by Sir Leonard Rogers. He discusses beriberi, pellagra, and nutritional anemias, endemic dropsy and other conditions due to faulty nutrition. One small paragraph in this section reveals a need for vigorous action for the betterment of the nutrition of tropical peoples. Dietetic malnutrition, Sir John considers, is the most important of the tropical diseases. It causes lifelong disablement of hundreds of millions of people, and is indirectly

responsible for millions of deaths every year. It is so common in some parts of the tropics that it is regarded as the normal condition of the people. The extensive planning of world civilization in the future which is now going on should make sure of the removal of this kind of underlying cause of disease. It is, as the careful rationing system in Britain during this War has shown, by no means confined to the tropics.

Many general practitioners will find useful the final chapters on the use of the microscope and on diagnosis. If they add to this book the study, suggested by its authors, of the *Tropical Diseases Bulletin*, they should be well supplied with up-to-date information. For the abstracts of world literature printed in the *Tropical Diseases Bulletin* are unique in that they are the critical work of experts, among whom are the authors of this book, so that they form a supplementary text-book which is continually being brought up to date.

G. LAPAGE

CHEMISTRY OF MILK AND MILK PRODUCTS

A Textbook of Dairy Chemistry

By Edgar R. Long. Second and revised edition. Vol. 1. Theoretical. Pp vii+196. (London: Chapman and Hall, Ltd., 1944.) 13s. 6d. net.

JUNIOR students of dairy science are at present ill-provided with competent, up-to-date textbooks. The War has doubtless been responsible for the lag in getting the results of the considerable advances of recent years into a form useful for the younger student.

In dairy chemistry the situation is now much easier than in dairy physiology or dairy husbandry. We have the thorough revision (1942) of Richmond's "Dairy Chemistry" by Elsdon and Walker, a valuable text with a strong analytical flavour, and now the volume under review, written by one of our most experienced teachers of agricultural chemistry. The present edition is a fairly complete revision of the theoretical part of his 1930 volume.

It is a straightforward, sensible handbook for students of intermediate grade, is well documented and demands no more than a fair elementary acquaintance with chemistry. Careful thought has clearly been given to providing a simple yet accurate, readable and up-to-date presentation.

Nevertheless, in one or two places revision has faltered. The table on p. 55 purporting to show the vitamin content of various types of milk and dairy products certainly requires overhaul. Instead of indicating vitamin content by vague adjectives such as 'good', 'fair', 'slight', etc., use should be made of the range of quantitative data now available (in μgm or in international units) for most, though not yet all, dairy products. One could also have wished that the paragraph on the effect of heat on milk had been brought closer to date and that recent sources had been quoted, though the author does in fact reach the right conclusion in his final sentence (p. 109). These small blemishes are perhaps the more evident since the background is generally so well informed.

The book can confidently be recommended to dairy diploma students and to those engaged in the dairy industry who require a sane and dependable chemistry text-book.

H. D. KAY

Catalogue of Lewis's Medical, Scientific and Technical Lending Library

Part 1 Authors and Titles, Part 2 Classified Index of Subjects, with Names of Authors who have written upon them. New edition, revised to the end of 1943. Pp. xiii+928 (London: H. K. Lewis and Co., Ltd., 1944). To Subscribers, 12s 6d net, to non-Subscribers, 25s net.

THE difficult task of cataloguing the great variety of scientific books in this remarkable library has been well done. Probably the most difficult part of it was the compilation of the subject index (Part 2). This section indicates the wide range of the library, for the headings in it extend from chemistry (9½ pages) to travel, and from sugar to suicide. It covers, in fact, practically the whole range of science. Together with the alphabetical list of subject headings, it forms a valuable reference list of the authors of important works on the various branches of science up to the end of 1943. Subscribers receive, each month in normal times and quarterly at present, lists of new books and editions added to the library, which keep them in touch with new publications.

It is not surprising that "Lewis's" is used by scientific workers of very varied interests and by book clubs, medical and scientific societies and by the research departments of many industrial organizations. The preface to this catalogue suggests that we owe the foundation of "Lewis's" to Carlyle, whose complaints about the loss of time involved in waiting for books at the British Museum gave us the London Library as well, so "Lewis's", originally mainly medical, came into being and now provides a unique general science library service which has features no other scientific libraries possess. The subscriber will not, however, be able to borrow scientific books in foreign languages, unless these have been translated. Many subscribers have hoped, and still hope, that it will eventually be possible to remove this restriction.

It is never easy to assess in a few words any library service. So much depends upon atmosphere, the spirit of service and the willing co-operation of the borrower in seeing that the necessary rules are obeyed. But the long experience and wise management of "Lewis's" have surmounted the potential causes of complaint and failure. This catalogue is, incidentally, a tribute to their quality as publishers. It is yet another example of the high degree of attractiveness, utility and good printing which can be attained under the authorized economy standards of war-time book production.

The Natural Order

Essays in the Return to Husbandry. By Edmund Blunden, H. J. Massingham, B. D. Knowles, Philip Mauret, Philip Oyler, L. F. Easterbrook, C. Howard Jones, J. E. Hosking, Lord Northbourne, Michael Graham, Rolf Gardiner, Adrian Bell, C. Henry Warren, the Earl of Portsmouth. Edited, with an Introduction and Notes, by H. J. Massingham. Pp. vi+178 (London: J. M. Dent and Sons, Ltd., 1945). 7s 6d. net.

THIS volume, containing some fourteen essays, has been written by lovers of the country, its agriculture, rural tradition, and way of life. No doubt it will be read with pleasure and approbation by those of kindred mind. It *should* be read seriously by a much wider section of the community, in particular by those who, by political action, mould

the national way of life. It may be argued, of course, that there is a sense in which everything that man does is part of the natural order. But the meaning intended is made quite clear in the introduction and in the integrated series of essays presented. The basic plea is for a return to good husbandry, for a personal understanding of the land, and a knowledge of how it should be used so that its fertility may be conserved and used to best advantage; it is a plea for good work performed for its own sake and because it is part of a good way of life; it is a plea for the retention of a civilization that is rapidly being submerged in the modern mechanized, urbanized development; above all, it is a plea for the fair treatment of the land (and those who work on it) or which so much that is good in our national life depends. The theme is fully explored in essays contributed by authors each with particular experience of his own subject. Here and there, no doubt there are evident overstatements, and occasional pseudo-scientific assertions which would have been better omitted. But these can well be overlooked in a book that is so unmistakably sincere. More is the pity that so much that could be ideal in life is unlikely to be realized.

The British Journal Photographic Almanac and Photographer's Daily Companion

With which is incorporated the Year Book of Photography and Amateurs' Guide and the Photographers' Annual, 1945. Edited by Arthur J. Dalladay. Pp. 388+31 plates (London: Henry Greenwood and Co., Ltd., 1945). Paper, 3s 6d net, cloth, 5s net.

THE "British Journal Photographic Almanac" is one of those books that few photographers can afford to be without. This applies to all those who handle cameras or photographic materials, whether they be amateurs or professionals, interested in pictorial photographs or research involving the use of light-sensitive materials. The volume is published annually and, while much of the contents is little changed from year to year, a series of up-to-date articles forms an important feature of each issue. This year there is an editorial which deals with the development of photography from the days when a photographer started by serving an apprenticeship to learn the technique, until to-day when photography is being used more and more for scientific purposes where a knowledge of the behaviour of photographic materials is a necessary preliminary. The plea is for the professional photographer of the future to learn more of the science of photography and rely less on rule of thumb methods. Is it not even more important that the would-be research worker should be taught more of the science of photography so that he can should the need arise, use photography intelligently as a tool to assist his research?

Other articles of interest are "Photograph Dermatitis" in which the requirements of preventive treatments are considered and formulae given for various preparations, "Colour Photography Practice" deals with the pre-war, war and post-war periods in the principal countries, mainly from the point of view of the commercial and advertising trade, "pH Measurement by Indicators" is written for photographers and deals with the subject from the point of view of photographic solutions. The remainder of the volume is taken up by formulae, general information, advertisements and illustrations etc., so well known to those familiar with previous issues of the almanac.

ISOLATION OF THE MAMMALIAN COLOUR RECEPTORS WITH MICRO-ELECTRODES

By PROF. RAGNAR GRANIT

Nobel Institute for Neurophysiology, Karolinska Institutet, Stockholm

IN 1943 I gave a summary¹ in *Nature* of my analysis of the retinal colour receptors isolated with micro-electrodes on the optic nerve reached from the inside of the opened bulbs of various light-adapted animals, anesthetized or decerebrated. Two types of responses were found to be represented by single fibres: narrow bands of sensitivity located in three preferential regions of the spectrum, 0.600–0.580 μ (red-yellow), 0.500–0.540 μ (green) and 0.460 μ (blue). These were called *modulators*. In addition, there was a broad band, called the *dominator*, with maximum at 0.560 μ , and a distribution of sensitivity corresponding to the human photopic luminosity curve. The dominator was held to mediate the sensation of white. The modulators were located by a 'chance method' of surveying a large number of light-adapted retinæ. It seemed desirable to check these results by devising a method for removing this element of chance, and at the same time to find out whether the dominator could be regarded as the sum of a number of modulators. To this end a method of selective adaptation was employed. The new results obtained will now be briefly summarized. They represent my general solution of the problem and have confirmed and extended the earlier results.

Decerebrated cats were used as experimental animals. A special colorimeter, designed by Dr D. Wright of the Imperial Institute of Science and Technology, on the principles of his own well-known instrument², and constructed by Mr G. C. Ewton, was used for stimulation. In such experiments the micro-electrode records the impulses from convergence unit of the type shown to the right.

Fig. 1. There are connected to the same optic nerve fibre receptors which contain merely visual purple and receptors containing other colour-sensitive substances. The number of receptors is probably

Fig. 1. MICRO-ELECTRODE RESULTS FOR DARK-ADAPTED CAT. Large circles, averages for spectral sensitivity of dark-adapted cat's retina. Small black circles, Lythgoe's³ corrected curve for visual purple absorption. For significance of symbols and p - and i -curves, see text. Spectrum of equal quantum intensity diagram to the right illustrates convergence element picked up by micro-electrode on the optic nerve.

very much larger than in the diagram and the proportion of the two types is unknown and variable. In the dark-adapted state the highly sensitive visual purple completely dominates the results and gives the curve P (Fig. 1), based on some 1,320 readings, averaged into 179 values, again averaged to give the large circles around the curve. The small black points are Lythgoe's³ corrected curve for visual purple absorption, which is a little too low in the violet, as shown by Schneider, Goodeve and Lythgoe⁴. A slight effect of the dominator makes my curve a little too high in the yellow-red region.

If the eye be adapted to red, blue or green light, the curve P is reduced to p , by proportionate ordinates at all wave-lengths, since P represents a homogeneous substance. Hence

$$P/p = k \quad (1)$$

But if there are any other colour-sensitive substances (M), preformed or produced by visual purple, curve P does not drop to p but to some other curve U (Fig. 1). The modulators M are given by the difference between U and p , as evident from the diagram, or

$$M = U - p \quad (2)$$

In this case p is unknown, but the equation can be solved by giving it the form

$$M = U - P/k \quad (3)$$

P is obtained before, U after, selective adaptation, and k can be obtained from (1) by finding the spectral region in which selective adaptation has caused the largest drop of sensitivity, since in this region there was no substance other than visual purple to resist adaptation. This region will generally be found in the place where the letter p is inserted in the diagram (Fig. 1). All quantities of (3) are now known and the argument can be tested by experiment.

Equation (3) was solved in thirty-four experiments on the basis of some four thousand observations collected in 601 points on U -curves. Some 60 per cent of the U -series referred to isolated fibres, the rest to restricted activity. In 29 per cent the equation came out zero ($U = p$) and hence the micro-electrode had struck a unit with pure visual purple receptors. In the rest of the series the characteristic narrow modulator bands of sensitivity were obtained. Red adaptation gave green and blue modulators (the red ones wholly suppressed), blue adaptation merely red modulators, green adaptation gave red, blue and green modulators.

The averaged modulators are shown in Fig. 2, in which the outer contours indicate the dispersion. The narrow red modulators were of two types with maxima at 0.600 μ (red) and 0.580 μ (yellow) respectively, the former type more common. Most green modulators overlapped and had maxima at 0.540 μ , some at 0.520 μ , and two of them were of the type previously described as narrow visual-purple curves. These may be lacking in pure cone eyes. All these modulators have been seen before in different types of retina, analysed by the earlier 'chance' method¹. Most blue modulators had their maxima at 0.460 μ (blue), one at 0.440 μ (violet). They were very narrow bands. Errors of measurement increase from red to the blue end. On account of the steepness of the modulator curves the maxima are fairly well definable.

The averaged modulators of Fig. 2 are too narrow to add up to a cat dominator. It is clear that impulses also must be delivered up the optic nerve by modulators with 'legs' outside the averages. The

Fig 2 AVERAGES OF INDIVIDUAL MODULATORS IN THE THREE PREFERENTIAL REGIONS. Outer contours indicate dispersion. Spectrum of equal energy.

greater the number of modulators added, the greater has to be the spectral area allotted to each preferential region. In Fig 3, I have synthesized the cat's dominator, as obtained experimentally with single fibres some years ago⁵. This has a hump at 0 600 μ . The circles refer to the readings, the thick line to the theoretical curve obtained by adding the R and G curves. It is a remarkable fact, demonstrated by Wright⁶, that if the human photopic luminosity curve be determined with a sufficiently small stimulus, imitating the micro-electrode recording, it too has a hump around 0 600 μ , and, in fact, fits my synthesized curve for the cat almost exactly.

In Fig 4, I have synthesized the human photopic luminosity curve with three 'fundamental sensation curves' for R, G and B, and indicated the red and yellow modulators adding up to the R curve. These fundamental sensation curves correspond fairly well to those recently obtained by Walters⁷ on the human eye. In his work will be found a summary of the earlier attempts to define the fundamental sensation curves.

Now these fundamental sensation curves do not exist, except as mathematical entities. Nature uses a six- or seven-colour mechanism made up of narrow modulators, two red, two blue, two or three green. In addition, many of these modulators form fixed groups responding as *functional units* with the [dominator distribution of sensitivity. Despite considerable

Fig 3 CIRCLES, AVERAGES OF FOUR PHOTOPIC DOMINATORS OF CAT. Curve D, synthesis of cat dominator by adding grouped modulators in the red (R) and the green (G) and plotting their sum in per cent of maximum. Spectrum of equal energy.

experience in recording from single fibres, I have never seen three 'fundamental sensation curves', but merely dominators and the narrow modulator localized at the three preferential regions. The trichromatic theory is therefore to be regarded as a convenient first approximation expressing the spectral areas covered by the three groups of modulators in terms of gross averages.

The existence of families of modulators, located in three preferential spectral regions, makes the extraordinary capacity of the eye to discriminate colour intelligible. In Fig 5, Wright and Pitt's⁸ measurements of colour discrimination are found. These show maxima of discrimination (minima in the curves at 0 580-0 600 μ , where the red and yellow modulators overlap and intersect with the green ones, at 0 480-0 510 μ , where the red, green and blue modulators intersect and rise, as well as at 0 450-0 440 μ , suggesting that two blue modulators, the blue proper and the violet one, overlap in this region, as also

Fig 4 SYNTHESIS OF HUMAN PHOTOPIC LUMINOSITY CURVE (D), AS DETERMINED BY COBLENTZ AND EMERSON⁹ ON 125 OBSERVERS. D is the sum of three fundamental sensation curves, R, G and B, which are summed modulators as indicated for the R-curve by M_r and M_y . Spectrum of equal energy.

shown by the experiments. The broader green modulators keep the curve fairly low in the green region, though not as low as in the regions where many narrow modulators of different type overlap.

Colour blindness is easily understood as a consequence of the absence or diminished number of certain modulators, anomalies as differences in the relative number. The very essential fact that colour blindness in most cases goes with retained sensation of white follows from the experiments, which have shown that the broad dominators responsible for the photopic luminosity curve are much easier to demonstrate than modulators. In most diseases leading to colour blindness of the acquired type, white is likewise seen despite absence of sensations of colour. This suggests that the isolated modulators, responsible for colour vision, are far more sensitive to disturbing agents than the aggregates assumed to make up the dominators. Since dominators are easier to obtain and hence probably commoner than the modulators, it seems natural that a slight reduction of the number of isolated modulators will suffice to cause colour blindness, but that for white-blindness nearly all structures must be affected.

Fig 5 HUMAN COLOUR DISCRIMINATION ACCORDING TO WRIGHT AND PITT*

There are also minor differences in the location of the photopic luminosity curves between protanopic and deuteranopic colour blindness. These are best explained as differences in the proportions of the modulators making up their aggregate dominators.

Since the modulators, which are the *physiological units of colour reception*, represent a finer mechanism of colour reception than the one envisaged by the chromatic theory, it is perhaps for this reason that colour matches with three primaries never are perfect in saturation. Nature uses a greater number of primaries, at least six or seven modulators, and, possibly, a still greater number of narrow sensitivity bands within the three preferential regions of the spectrum.

A full account of this work will be published in *Neurophysiol.*, vol 8, 1945.

THE FUTURE OF X-RAY ANALYSIS*

By PROF. J. D. BERNAL, F.R.S.
 Birkbeck College, London

[HAVE been out of contact with X-ray analysis for the last six years, this is both an advantage and a disadvantage. Because I know little of its present state, I shall not fail to see the wood for the trees, I can follow the trends, but I am certain to be wrong in detail.

The predictable future is the rational projection of the past and the present, so I shall begin by tracing the major stages of X-ray analysis in the last thirty-five years. The first stage, the Bragg period, as it may well be called, was that in which all the basic structures were worked out. The first edition of "X-Rays and Crystal Structure" contained a specimen of every basic type. It could not have been realized at the time, but every structure since has been an elaboration of one or other of these types. The same true of methods, all were then known in embryo. The next period was one of rapid development, the locates were elucidated, then the alloy structures, and a beginning was made in organic compounds with long-chain compounds, aromatics and fibre structures. The number of papers on crystal structure rose rapidly until 1933, then fluctuated about a mean. This date may be taken as the end of the heroic age

of X-ray analysis. It was then realized that the new structures would be essentially like the old ones, and interest was directed towards new and more complex phenomena. From then until the outbreak of war, activity centred round such matters as order-disorder transformations, isomorphous replacement, equilibrium diagrams and biological molecules. During the War there has been an almost complete cessation of academic crystallography, but X-ray analysis has given valuable assistance to other branches of science and industry.

What will happen when it is possible to resume a rational programme of research after the War? The only guarantee of the progress of applied science lies in keeping a proper balance between it and pure science. I believe that 'pure' X-ray analysis will find new fields more and more complex structures, and show a great development of analytic methods, while 'applied' X-ray analysis will become as essential a tool for other fields of research as the microscope and the spectroscope have been in the past.

Substances to be Investigated

In inorganic chemistry not even the simpler fields have been completely covered, but enough has been done to consider the rest as 'mopping-up' operations. There are still, however, a few groups of compounds not well understood. The first is that of the compounds of boron and carbon with other light elements. These have homopolar bonding, are very hard, and have high melting points. They may contain interstitial metal atoms, and their electrical properties are interesting. Diamond is the only one that has been worked out properly. Another group that will claim attention is the sulphides and the sulpho-salts—compounds of sulphur, arsenic and antimony with metals. They are of major interest to the geochemist, and may throw light on the genesis of metallic ores. There is also work to be done on the oxy-acids, and on the types of Wernerian complexes, the variety of which verges on the organic.

In the field of organic chemistry, there is no future in attempting to find the structures of all crystalline compounds. The basic elucidations of some types—aromatics and sterols—have given keys to organic structure determination, and interest will centre on the nature of the bonds between atoms in the molecules and those between neighbouring molecules. Chemists outnumber crystallographers by about fifty to one, so that crystallographers must make the best use of their time, they must tackle things with soluble structures, but things the chemical nature of which is unknown. One of the triumphs of crystallography during this War has been the complete determination of the structure of one extremely important compound before the chemists had unravelled its structural formula. Many substances of great chemical difficulty will be tackled in the same way.

Beyond the ordinary compounds of organic chemistry there lies the wide range of complicated biological molecules of which the proteins are the best known but by no means the only type. Intense work will undoubtedly continue both on the crystalline and fibrous states of these compounds. The structure of the proteins, fundamental to the understanding of living processes, will not yield to X-ray analysis alone, the attack must be combined with biochemical, centrifugal, electrophoretic, electron microscope and other methods, but there is no doubt that X-rays will play a crucial part in verifying all

* Substance of an evening lecture to the 1945 Conference of the X-Ray Analysis Group of the Institute of Physics, delivered at the Royal Institution on April 12.

hypothetical structures put forward on any other basis

Physics

In the field of X-ray physics, interest will be concentrated on the secondary phenomena of diffraction thermal spots, side-bands, Preston streaks, the effect of temperature on the 'micellar' structure of real crystals. There will be the development of such things as Guinier's central-spot methods, photography at high and low temperatures, high-intensity sources. X-ray tubes in current use are still at the Röntgen level, and a revolution in camera- and tube-design may be expected very soon. Goldstaub and Guinier have already shown how the electron beam can be controlled as in an electron microscope and focused to a tiny spot, so that a current of 0.1 mA will do as much as 50 mA now. There is a trend toward the use of smaller cameras, and with better tubes time-exposures will become snapshots. Filters are anachronisms, and crystal-reflected, monochromatized radiation will be the rule.

There must be great development of analytic methods and means of calculation. We are only at the beginning of the development of mechanical and optical methods, and their improvement is very necessary as calculations are becoming a bottle-neck. There is no use in being able to take photographs in a few seconds if the calculations take months.

Applications

So far, I have spoken only of straight structural analysis. There is another side to the story—the applications of X-ray analysis to other problems. This will form a larger and larger part of X-ray work. The difficulty has been that the X-ray tube and camera were considered a mysterious and dangerous instrument. People have had three hundred years to get used to the optical microscope, but only thirty to get used to X-rays. The result is that X-rays are not utilized to anything like the extent that they should be. Only the crust has been broken in their industrial application.

I see two fields of organized effort. First there will be highly concentrated specialist X-ray laboratories in universities and big firms. There will be comparatively few of these, not more than one per university or institute. Secondly, there will be standardized equipment available in every laboratory that can usefully employ it. X-ray tubes will be as universal as spectroscopes, and powder cameras as microscopes. The field of X-ray analysis ranges from well-established techniques, as in the metal industry, to the almost unexplored problem of humus formation.

In the metal industry many standard techniques are in use, such as those for the identification of materials, measurement of strain, measurement of grain size. There is considerable use of X-rays in the refractory, ceramic and glass industries—as a rough generalization one might say that the closer an industry is to metallurgy, the more satisfactory is the situation. In cement manufacture, X-rays are used chiefly for quality control, and the industry would benefit greatly from an extension of their use to the examination of raw materials and of the setting process of cement. In the chemical industry a start has been made, but it is only a start, even in the heavy chemical field. Light chemicals have scarcely been touched, and the food industry offers a great opportunity. It is true that the substances to be

investigated are 'messy', and do not give good photographs, but there is no reason to suppose that the mathematics of their interpretation cannot be worked out.

In agriculture a small beginning has been made in the identification of soil minerals, but the whole question of soil profiles and the formation of humus remains to be examined. Nagelschmidt's and Mathieu's work in this field marks the beginning of the physical understanding of soils, and its development will lead to the replacement of the present 'mysticism' by knowledge. In geology geophysics and geochemistry X-ray analysis will have a great part to play. Goldschmidt's study of mineral strata and similar problems will lead to a rational development of geophysics. Though it sounds a contradiction in terms, what is needed is an Institute of Experimental Geology, where geological processes can be reproduced and studied in detail.

The Task of Crystallographers

It would be futile to consider these prospects without discussing the means for their realization. We have a great task before us if our opportunities are not to be missed. First, we must ensure that there are enough trained people. I hope that, after the War, X-ray analysis will have a larger part in university curricula. A little of it is taught somewhere, usually in chemical or geological departments in most universities, but the only full-scale course is at Cambridge. It is up to the universities to provide greater facilities for both graduate and undergraduate instruction. The Cambridge summer schools in industrial crystallography have made a good start and should be a regular, but probably not a permanent, feature. When crystallography has found its proper place in the normal curriculum, such schools will be needed for whatever is the new subject at that time.

Secondly, there is need for improvement and standardization of apparatus. We know how difficult it is to get apparatus made to our own specifications, since the numbers required are not large enough to make commercial production profitable. We must hope that standardization will remedy this, and that it will no longer be necessary to put up with home-made apparatus. We must first, however, develop reasonable and practicable designs for all necessary apparatus. Our laboratory workshops will still be necessary, but they will be free to work on new equipment instead of spending most of their time making copies of old apparatus. An interesting thing I have noticed is the slowness of the diffusion of material techniques from one laboratory to another, even in the same country. When refitting after the War, we must make the best use of ideas that have been developed in countries other than our own. It is interesting to find that the X-Ray Analysis Group of the Institute of Physics is working on a new method of agreed specifications.

Thirdly, there is the question of publication. Before the War, crystallographic papers appeared in fifty-seven different journals, and of these only the *Zeitschrift für Kristallographie* was devoted wholly to crystallographic work. We must work for some sort of centralization. One big task is the tidying up of existing knowledge. No one has time to read everything published. A good deal of early work may be wrong, and in any event the detailed measurements

are inexact. We need some sort of a permanent up-to-date loose-leaf 'Strukturbericht'—an X-ray analogue of Groth's "Chemische Krystallographie". In pre-war days Germany was the major stronghold of such systematizing activity; but it is unlikely to be so again, at any rate for some time after this War, so we must share it out. The "X-Ray Index" is a small beginning. Crystallographers in the past have been good at co-operative international activity; the "International Tables" are one outstanding example. We may confidently expect similar success in the future.

International Aspects

Soon it will be possible to resume international contacts. In Great Britain we do not realize how much X-ray analysis has been a British subject. It has struck no deep roots in other countries, but we shall all be the gainers if others work as intensely as we. I look forward to a spread of crystallographic activity all over the world, with increasing benefits to mankind.

ANOMALOUS INACTIVATION OF HEAVY METAL ANTIFOULING PAINTS*

By Dr. G. H. YOUNG and G. W. SEAGREN

Mellon Institute, Pittsburgh, Pa.

THAT ordinarily effective antifouling paints occasionally show very poor performance, or suddenly begin to foul severely after a period of satisfactory functioning, is an observation familiar to every user of marine paints. In the case of compositions carrying metallic copper, such failures have been almost universally attributed to 'galvanic coupling' with the steel hull—the implication being strong that such paints can and do act in a manner entirely analogous to a gross sheet of copper. In an effort, therefore, to establish the real truth of this matter, the phenomenon of inactivation with both metallic copper and cuprous oxide paints has been under study by us for some time. We have already shown that accidental or deliberate contact of the steel hull with either type of copper-bearing paint can lead to serious pitting at the contact point and to accelerated corrosion attack at adjacent bare areas or 'holidays'^{1,2}. An equally if not more serious result of failure to separate properly the antifouling paint from the steel hull by adequate barrier coats is a decreased effectiveness³ or even complete inactivation of the antifouling coat¹.

While certain of our experiments are still uncompleted, we have already established that contact-inactivation can happen with cuprous oxide paints as readily as with metallic copper paints¹. The antifouling efficiency of both types is rapidly lost if they are applied over bare steel; within three months of immersion they are as badly fouled as are control panels carrying no antifouling paint. As many of these formulations have demonstrated satisfactory antifouling action if applied in the conventional manner over the usual primer and anticorrosive coats, or if applied to wood, it seems established that their immediate proximity to corroding steel is

FIG. 1. CHARACTERISTIC BANDED FOULING ADJACENT TO BREAK IN PAINT FILM.

responsible for the inactivation. It is important to note that this inactivation seldom manifests itself in the first month of exposure; this fact alone throws doubt on simple 'coupling' as the causative factor, because all fouling exposures involving unpainted copper-steel couples show immediate fouling of the 'cathodically protected' copper.

The observation—first made by us in 1942 in connexion with a series of immersed painted steel panels racked on 'Micarta' strips which in turn were bolted to plain iron angles—that 'run-down' of iron corrosion products over an antifouling paint inactivates the latter has undoubtedly been made by others, although we find no reference to it in any published reports. It is our belief that many cases of anomalous inactivation may be better attributed to this effect than to 'coupling'.

Selective Fouling

The occurrence of fouling in 'bands', either horizontal or vertical, near gross breaks in antifouling paint film on test panels where corrosion is actively going on has been the subject of much speculation². Several of our test series show this phenomenon markedly.

The North Florida Test Station exposure site at Daytona Beach, Florida, is located near the mouth of an inlet; the tidal action is such that a maximum velocity 'up-stream' approximating to 4 m.p.h. when the tide is coming in is attained; this is followed by a period of relative quiescence, then the current flow reverses, reaching a 4 m.p.h. velocity 'down-stream' at low tide. Thus, tidal action is such that a semi-stratified layer of water sweeps across the face of the test panels except when excessive wind and wave action produces turbulence and counter-currents. Accordingly, corrosion products originating at bare areas or mechanical breaks in the film may be swept out and across the surface of intact paint, in a horizontal band roughly the width of the corroding spot. Photographs of several test panels demonstrating the phenomenon are presented in Fig. 1.

Similar observations have been made at Kure Beach, Wilmington, N.C., where, however, the current flow is continuous, and in one direction only; here the area 'down-stream' of a corroding spot is always rust-stained and tends to foul well in advance of the 'up-stream' area.

We have observed the phenomenon taking place in substantially a vertical line with another series of panels bolted to, but insulated from, an unpainted steel overhead member. When fouling began, it was always the area immediately adjacent to the support at the top which fouled first, the fouling band being

* Contribution from the Stoner-Mudge, Inc., Multiple Industrial Fellowship on Protective Coatings at Mellon Institute.

Fig. 2. BRONZE ANTI-FOULING PAINT.

as much as two or three inches wide across the top of the panel. Fouling tends to run vertically on panels exposed at mean tide-level, where the air-water interface actually moves up and down as the tide shifts. We have occasionally seen manifestations of the phenomenon on ships' hulls, where rusting and corrosion 'top-side' at a bilge port cause run-down and staining of the antifouling coat at the boot-topping zone; fouling on the stained areas usually precedes that on 'clean' paint.

Reaction with Iron Corrosion Products

There is admittedly some question as to the solubility of iron corrosion products in sea water. Wesley and Lindsley⁴ have determined the equilibrium solubilities of ferric iron in a synthetic sea water and concluded that only a fraction of a part per million could exist in solution at pH 8-8.3, normal for sea water. Despite this finding, there appears to be good evidence that iron in soluble form can and does exist in natural sea waters at concentration levels many orders of magnitude higher than predicted by Wesley's calculations. Thus, ZoBell⁵ has shown that up to 1,000 p.p.m. of ferric iron can be held in natural sea water nutrient solutions in the form of organic complexes.

Wesley himself states that, in the pH range of 7-8, 60-6,000 p.p.m. of dissolved ferrous iron is theoretically possible. This fact is important, for the *slime film*, which blankets all submerged surfaces in a matter of hours, or at most days, is characterized by a pH of only 6.3-7.6, and even lower values have been recorded. Thus ferrous iron, at least, could be concentrated in organic detritus or slime film to

values in the range of 1,000 p.p.m. This is, of course, an oxygen-deficient zone by virtue of the organic matter present; there is thus no reason to predict instantaneous and complete conversion of ferrous to ferric iron in the slime film region. ZoBell says both ferrous and ferric iron are found in natural sea water, and makes the important observation that "iron, like aluminium compounds, precipitates from solution and thus inactivates toxic agents such as silver or copper . . .".⁵

As we see it, the stream of soluble iron complex is washed along and through the slimy interface region (faster in the direction of current flow), where it reacts with and precipitates the dissolved copper; the result is an 'inactivation' of the antifouling paint. With highly gelatinous, permeable paint films, copper precipitation can take place in the body of the film itself⁶, and even at the steel-paint interface in the absence of a barrier film.

Effect of Accidental Contact with Corroding Steel

We have also attempted to determine the possible effect of accidental contact of steel bolts, anchor chain or the like against an antifouling coat on a wood hull. For this purpose we employed seasoned panels, 8 in. $\times$ 12 in. $\times$ $\frac{5}{8}$ in., coated with three coats of the two selected test paints. To these panels were attached cleaned and weighed medium carbon steel tablets, 2 in. $\times$ 4 in. $\times$ $\frac{1}{8}$ in. drilled with a $\frac{7}{8}$ in. hole at the centre, in the following several manners:

(1) directly in contact with the paint face, attached with steel bolts and nuts;

Fig. 3. CUPROUS OXIDE PAINT.

RESULTS OF FOUR-MONTH IMMERSION OF PAINTED WOOD PANELS WITH ATTACHED STEEL TABLETS

Panel No.	Paint system	Tablets attached	Fouling observations	Wt loss (gm) of duplicate steel tablets
1	Metallic copper paint	None	No fouling	
2		Method 1	Fouled over an area about 2 in around the tablets	9.3-10.0
3		Method 2	Slight fouling immediately adjacent to tablet	6.6-6.7
4		Method 3	Same as panel 3	4.9-5.0
5	Navy Formula 16	Method 4	Same as panel 3	4.6-4.5
6		None	No fouling	
7		Method 1	Fouled over an area about $\frac{1}{2}$ in around the tablets	5.1-4.9
8		Method 2	Same as panel 3	6.1-6.1
9		Method 3	Very slight fouling not associated with tablets	6.0-6.1
10		Method 4	Same as panel 9	6.8-5.3

(2) separated from the paint face by 2 in $\times$ 4 in $\times$ $\frac{1}{8}$ in 'Formica' spacers, both attached with steel bolts and nuts,

(3) separated as in (2), with 2 in. $\times$ 4 in $\times$ $\frac{1}{8}$ in Vinylite⁷ spacers, both attached with steel bolts and nuts,

(4) separated as in (2) with 2 in $\times$ 4 in $\times$ $\frac{1}{8}$ in. Formica⁷ spacers, both attached with bolts machined from cellulose acetate rods and steel nuts (This arrangement positively guarantees that no accidental contact of paint to steel can take place)

As test paints we employed a formula containing approximately 4.8 lb per gallon of metallic copper, with which we have had considerable experience^{1,2}, and Navy Formula No 16, which is based on cuprous oxide as the toxic agent⁷. Several panels carrying no attached steel tablets were included as controls

The panels were immersed at Daytona Beach, Florida, during the period March 10-July 10, 1944, after which they were removed, photographed, and returned for dis-assembly and study. Their appearance after the four months' exposure is shown in Figs 2 and 3. Weight loss data on the tablets are summarized in the accompanying table (above)

Conclusions

The following observations appear to us to be significant

(1) Only in the case of non-insulated contact direct to the face of the metallic copper formula was there an appreciable inactivation for finite distances from the bare steel, this distance was of the order of 2 in nly.

(2) The general antifouling characteristics of the remaining panels were roughly the same, and probably not significantly different from the controls. As the steel tablets were $\frac{1}{8}$ in removed from the paint-water interface, it would appear that diffusion of iron corrosion products into the interface zone, from even such short distance outside it, was insignificant

(3) The weight loss of the tablets attached directly to the metallic copper paint was significantly greater than for the remainder. This fact almost certainly indicates that here a contact-couple effect was operative,¹ the phenomenon has been discussed elsewhere²

(4) The average loss of weight of all the remaining tablets was approximately 5-6 gm, and the figures were in excellent agreement. This finding gives a calculated rate of corrosion of 100 mgm per sq dem per day. Previous studies³ on the corrosion-rate of medium carbon steel in sea water at Kure Beach, C, where no antifouling paints were in the immediate neighbourhood, gave a value of 22 mgm per sq dem per day. It thus appears that all our tablets corroded at a rate about five times the normal rate. The conclusion seems obvious that copper, migrat-

ing out of the interface region, was deposited on the steel, from which severe local-couple acceleration resulted. It is important that this phenomenon took place without any direct contact to the paint films. It is completely predictable on the hypothesis of mutual interaction of soluble iron and copper, which we advanced earlier

As a practical matter, it would thus appear that accidental contact of chain, rudder posts and similar ironware with the antifouling paint on a wood hull would have very little deteriorating effect on antifouling efficiency unless the contact area be large. Certainly, the likelihood of overall inactivation is extremely remote

NATIONAL FLOUR (80 PER CENT EXTRACTION) AND BREAD IN BRITAIN

Seventh Report from the Scientific Adviser's Division, Ministry of Food

THE extraction of national flour was reduced from 82½ per cent to 80 per cent on January 1, 1945. A survey of this 80 per cent flour has been carried out on similar lines to that of the 82½ per cent national flour survey¹. Samples received from controlled mills were examined weekly for colour index and granularity and at frequent intervals for vitamin B₁, fibre, ash, calcium, iron, riboflavin and nicotinic acid, as described in the sixth report¹, with the exception that fibre was determined only on samples sent by Ministry of Food inspectors and calcium was determined only once in four weeks. In addition, about forty loaves were baked each week from different flour samples

By February 12, the quality of the new flour was approaching something like constancy (although it can still be improved considerably) and the present report describes the results obtained in the period of twelve weeks from this date to May 5. During this time, 2,943 samples of flour were examined

Composition of the Grist

The average composition of the grist used for milling the flour, calculated fortnightly during the period from data supplied by the millers and accompanying every sample, was as follows (Table 1).

TABLE 1

Fortnight beginning	Average composition of grist (capacity basis) of samples analysed			
	Manitoba wheat, %	Home grown wheat, %	Other wheat, %	Barley and rye, %
Feb 5	58.6	35.8	5.4	0.2
" 19	59.6	36.2	4.1	0.1
March 5	59.9	36.5	3.5	0.1
" 19	60.7	36.5	2.8	0.0
April 2	61.2	35.7	3.1	0.0
" 16	60.2	35.0	4.8	0.0

The 'other' wheat was principally Plate. The proportion of Manitoba is now about 3 per cent higher than in the average grist used for milling the 82½ per cent national flour (September–December 1944). This change is reflected in the average protein content of national flour, which was 11.6 per cent in 82½ per cent flour and has risen slightly in 80 per cent flour, being 11.76 per cent at the beginning of the survey, and 11.91 per cent in the fortnight beginning April 2, 1945.

Effect of Addition of Imported White Flour and of *Creta Praeparata*

The flour as supplied to the baker contained approximately 12½ per cent of imported white flour during the first four weeks of the present survey and 15 per cent thereafter. The addition consisted, on the average, of 13 per cent of Canadian and Plate flour, plus 1.8 per cent of United States flour. Owing to the high iron content of the latter, and the low fibre content of the white flours, the effect of the addition was not wholly negligible, in the tables of results which follow, the data presented relate to the flour as supplied to the public, the effect of the additions on the flour as milled is explained in footnotes. The addition of 7 oz. of *creta praeparata* per 280 lb. sack of flour increases the ash content of the flour by about 0.12 per cent.

Colour Index

Bran speck contamination was judged on the same scale as that used and described for the 82½ per cent survey (namely, 0 represents a white flour free from visible bran specks, and 100 represents a national average 85 per cent flour—capacity basis—as manufactured during July–September 1944). The percentage of all samples examined week by week that fell within the various colour index classes is shown

in Table 2 for the first three weeks and for three recent weeks, together with the average colour index values, calculated on sample and capacity bases. (The term 'capacity basis' is used frequently throughout this report. It means that the particular characteristic—colour index, fibre, B₁, etc.—is weighted for the output of flour from each mill. In calculating 'national average' figures it may be misleading to give equal weight to the result from a small mill and that from a large mill.)

TABLE 2

Colour index not exceeding	Weeks commencing					
	Feb 12	Feb 19	Feb 26	Mar 26	April 2	April 9
5	17	19	15	15	20	17
10	36	40	40	31	48	50
15	55	56	60	57	68	68
20	68	69	68	68	75	76
30	83	83	83	82	86	83
40	93	94	91	89	92	92
50	98	97	97	96	97	98
70	99	98	100	99	98	99
100	100	100	100	100	100	99
Average Colour Index						
Sample basis	19.9	19.8	19.8	21.2	18.5	18.5
Capacity basis	13.3	12.5	12.6	13.7	11.7	11.4
Number of samples	244	254	253	254	193	237

Thus the average colour index (capacity basis) has decreased from 37, the figure recorded during the last week of the 82½ per cent survey, to 11, that is, the amount of bran speck contamination is only about one third of what it was in 82½ per cent flour, or one tenth of that in the average 85 per cent flour.

Granularity

Every sample of flour received during the survey was sifted over a No. 10 standard bolting silk (aperture = 0.135 mm) under standardized conditions, using a mechanical sifter, and the percentage weight and the character of the fraction failing to pass through the silk (overtails) were recorded. Samples were encountered with up to 34 per cent tailing the silk, whereas others passed through entirely. The arithmetic mean of the percentage weight of overtails of 10 silk from 936 samples received during four consecutive weeks was 7.3 per cent, while the most frequent value was 5.5 per cent.

TABLE 3 FIBRE AND ASH IN 80 PER CENT FLOUR

	Week commencing										
	Feb 12	Feb 19	Feb 26	March 5	March 12	March 19	April 2	April 9	April 16	April 23	Av. 10 weeks
(a) Determined on individual samples											
Average fibre, %	0.20	0.23	0.18	0.19	0.20	0.22	0.20	0.24	0.21	0.21	0.21
" ash, %	0.76	0.79	0.74	0.75	0.72	0.76	0.79	0.77	0.75	0.79	0.76
" <i>creta</i> addition, oz./sk	5.7	5.4	5.1	5.1	5.4	4.9	5.0	5.2	4.4	6.5	5.3
Number of samples	13	13	14	15	11	15	10	10	12	16	
(b) Determined from composite samples (fortnightly)											
Fibre, %											
Sample basis	0.18		0.23		0.22		0.20		0.23		0.21
Capacity basis	0.18		0.21		0.19		0.17		0.21		0.19

(1) The fibre content of the flour as milled is approximately 0.016% higher than that given in the table on account of the presence of 12½–15% of imported white flour in the flour analysed.

(2) The figure for ash contains approximately 0.09% due to added *creta*. The statutory addition of *creta praeparata* is 7 oz. per 280 lb. sack of flour, the average value for samples from 231 mills analysed during the last six weeks of the present survey was 6.0 oz./sk.

TABLE 4

	Weeks commencing											
	Feb 12	Feb 19	Feb 26	March 5	March 12	March 19	March 26	April 2	April 9	April 16	April 23	April 30
Av B ₁ , IU/gm	0 77	0 77	0 78	0 80	0 78	0 80	0 80	0 77	0 82	0 81	0 77	0 79
Sample basis	0 77	0 78	0 80	0 81	0 79	0 81	0 81	0 77	0 81	0 82	0 79	0 80
Capacity basis	127	131	136	143	125	135	140	108	87	125	133	133

Note. The figures for average vitamin B₁ content above include approximately 0 01 IU/gm derived from added United States white flour

Fibre and Ash

Fibre and ash were determined on all samples sent by inspectors (about twelve samples per week). In addition, fibre was determined fortnightly on composite samples representing approximately 250 mills from these determinations, averages, on sample and capacity bases, could be calculated (Table 3)

Vitamin B₁

The weekly average values, on sample and capacity bases, of vitamin B₁ in the samples as received are given in Table 4

Riboflavin, Nicotinic Acid and Iron

The fortnightly average values for these constituents, on mill and capacity bases, are shown in Table 5

TABLE 5

	Fortnight commencing					Average for 10 weeks
	Feb 19	Mar 5	Mar 19	April 2	April 16	
Riboflavin, p p m sample and cap bases	0 8	—	0 8	0 75	0 8	0 8
Nicotinic acid, p p m, sample and cap bases	17	16	16	17	16	16 5
Iron, p p m Sample basis	15 8	16 5	16 4	16 5	15 8	16 2
Cap basis	15 8	16 8	16 5	16 7	15 6	16 3

Note. Added United States flour contains approximately 29 parts iron per million, while Canadian and Plate flour contain approximately 10 5 p p m, the iron content of the national flour, as milled before addition of imported flour is therefore approximately 0 6 p p m higher than the values given in the table. Any correction for nicotinic acid and riboflavin is well within the experimental error of the determination

Colour Index of Flour and Fibre Content

Since colour index is an estimate of the amount of bran in the flour, it should be closely related to the fibre content. Fibre determinations on 209 samples of 80 per cent national flour confirm this relationship (Table 6)

For flours with a fibre content of about 0 25 per cent or less, the colour index is probably a better estimate of the amount of bran in the flour than is the fibre determination

Colour Index of Flour and Vitamin B₁ Content

The relation between colour index and vitamin B₁ content was tabulated above for the most recent vitamin B₁ determination on samples from 283 mills

TABLE 6

Colour index	Average fibre content %	Average vitamin B ₁ content IU/gm
5	0 17 (26)*	0 80 (27)*
10	0 20 (35)	0 78 (68)
15	0 21 (28)	0 81 (60)
20	0 21 (23)	0 78 (37)
25	0 21 (21)	0 75 (19)
30	0 22 (12)	0 75 (20)
35	0 23 (11)	0 78 (9)
40	0 25 (11)	0 79 (15)
45	0 26 (12)	0 83 (1)
50	0 25 (11)	0 80 (17)
60	0 29 (6)	0 73 (8)
70	0 33 (4)	0 79 (1)
80	0 36 (2)	—
90	0 37 (3)	—
100	0 39 (4)	0 92 (3)

* The number of determinations is shown in parentheses

A similar conclusion to that drawn in the sixth report¹ is evident, namely, that there is little relation between colour index and vitamin B₁ for such a wide range of samples, that is, it is possible to combine good colour and a high B₁ value

Comparison of 80 per cent Flour with 82½ per cent and 85 per cent Flour

Average values for 80 per cent extraction flour are below set against values for 82½ per cent and 85 per cent extraction flours as given in the sixth¹ and fifth² reports respectively

TABLE 7

	80%	82½%	85%

Ash, %	0 76	0 88	0 98
Colour Index			
Sample basis	20	51	
Capacity basis	13	41	100
Granularity, av % wt over No 10 silk	7 3	9 8	15 5

Note. The above figures relate to national flour as received. The value for ash in the flour as milled (that is, before the addition of creta preparata and imported flour) is slightly lower, those of iron and fibre are slightly higher, as indicated in the relevant tables

Quality of Bread

Loaves baked from national flour survey samples During the period under consideration, 388 samples of flour were baked under ideal conditions in the laboratory and the resulting loaves judged for volume,

colour and quality of crumb, and were classified as follows

Quality of bread	Number of loaves	Per cent of total
Good	300	77.4
Fair-good	55	14.2
Fair	22	5.7
Poor	11	2.8

Survey of commercially baked bread During the same period, 775 samples of bread purchased from bakers in different parts of Great Britain have been examined and judged for quality (commercial standards) with the following results

Quality of bread	Number of loaves	Per cent of total
Good	87	11.2
Fair-good	366	49.8
Fair	218	28.1
Poor	84	10.9

Although there is a marked difference between the average quality of bread sold and the bread that could be made from the flour available, the great difficulties of the baking industry—particularly that of labour—must not be overlooked

This work was carried out at the Cereals Research Station, Ministry of Food, St Albans

OBITUARY

Dr. K. J. W. Craik

KENNETH CRAIK was born on March 29, 1914. He died as the result of an accident on V.E.-Day, May 8, 1945. Into this brief period he managed to pack achievements and promise far beyond the range of most people whose span of life is normal. His school was Edinburgh Academy. He was almost wholly on the Classical side. At seventeen he entered the University of Edinburgh. Here he read philosophy with distinction, was given his first taste of psychology by Prof. James Drever, and won the Hamilton and then the Shaw Fellowships. By now he had developed many hobbies, collecting all kinds of natural objects, constructing models, learning the accurate and minute use of tools, and developing a wide, lively and rather unconventional interest in the methods of natural science and the results of their application.

In the autumn of 1936 Craik joined the Cambridge Psychological Laboratory as a research student. It was his chief desire to undertake investigations which would bring together physical, physiological and psychological interests and methods in intimate relation. Naturally he turned to the study of the special senses. He chose 'visual adaptation' as his general problem, and devised and carried out many new experiments dealing with bright- and dark-adaptation, with those conditions at and above the threshold under which the human eye is most keenly discriminative, and with some of the phenomena of visual after-images. In 1940 he received the Ph.D. degree, and a year later, when he had considerably enlarged his dissertation, and added, in particular, a section describing a number of new and exceedingly ingenious scientific instruments for the investigation and measurement of a variety of sensory and motor functions, he was elected to a fellowship at St John's College. Under war-time arrangements, the fellowship was suspended, and Craik, still keeping his Cambridge

headquarters, embarked upon four and a half years of strenuous and devoted national service. In 1941 the Medical Research Council, for which he had carried out many of his most remarkable investigations, decided, with the concurrence of the University, to establish at Cambridge a Unit for Research in Applied Psychology. Its home was the Cambridge Psychological Laboratory, and Craik was made its first director.

No mere list of dates and honours can convey any adequate impression of Craik's vivid and vital personality, or of his promise and power. He would meet people of every rank and station in life, and of the most diverse interests and skill, and in a few minutes produce an unforgettable impression of unassuming but complete mastery. To him and to his work all three of the Fighting Services and several of the departments of civil defence owed far more than can yet be told. As his reputation rapidly grew and as more and more problems accumulated which required for their solution a knowledge of human responses to the signals and controls of the instruments of war, it became almost a matter of course in scientific and research units scattered all over the country, to say "Ask Craik, he'll know." He generally did. If he did not, he would set to work to find out. Wherever he was required he went with tireless spirit, and an indomitable good temper. He took the greatest risks, at sea, on land and in the air and enjoyed them all.

One remarkable character stamped almost all Craik's work. He would take perfectly specific questions, such, for example, as the most effective design of a particular radar display, and find in the answer some fruitful suggestions for fundamental scientific advance. At first, as a natural development of his earlier work, he was chiefly concerned with visual problems, particularly with vision at night or in conditions of bad visibility, with the design and placing of special lighting systems, and with how to arrange visual displays on many types of mechanical and electrical instruments so as to promote ready and accurate interpretation. In war and in peace, in the laboratory or in the world outside, visual signals and displays are generally used to guide operational control, and perhaps most frequently of all to set up voluntary movements in a human operator. Inevitably, therefore, Craik became more and more interested in the mechanics of bodily activity and the fundamental characteristics of voluntary movement. When the details of his work in this direction become publicly available, it will be found that they open up a vast, and largely a new, field of research.

Craik's contacts were wide and his friends many. But only those who knew him well at work, and at play, can fully appreciate the fineness of his mind and the complete honesty of his character. In experiment he was silent, absorbed, concentrated. In the workshop he showed amazing speed, unfailing resource and beautiful craftsmanship. Through many a long night of fire-watching he planned and constructed the instruments which he and others with him used to great effect. When the work was done, he flung himself into any game or discussion or party that offered, or rushed off on a journey or a visit with equal enthusiasm.

Craik's work will continue. There is no doubt about that. The Unit which he led is on the move. Whatever of good in scientific achievement it accomplishes will be the tribute which he himself would most have desired.

F. C. BARTLETT

NEWS and VIEWS

British Representatives at Soviet Academy Celebrations

AT the invitation of the Academy of Sciences of the U.S.S.R., transmitted through the Ambassador of the Union of Soviet Socialist Republics to the Court of St James, a party of scientific men and scholars left England for the U.S.S.R. on June 14 to participate in the celebration of the two hundred and twentieth anniversary of the founding of the Academy of Sciences of the U.S.S.R. The foundation of this Academy was in some measure due to the visit which Peter the Great paid to England in 1698, when he met men like Evelyn and Halley, who were then prominent members of the Royal Society of London. The following are taking part: Prof. N. K. Adam, Prof. E. N. da C. Andrade (representing the Physical Society, also the University of London), Prof. E. D. Adrian (also representing the University of Cambridge), Prof. J. D. Bernal, Prof. P. M. S. Blackett, Prof. Max Born, Prof. V. Gordon Childe (also representing the Royal Society of Edinburgh); Dr. E. M. Crowther, Sir Charles Darwin (also representing the Institution of Naval Architects), Prof. P. A. M. Dirac, Prof. F. G. Donnan (also representing the Chemical Society), Mr. W. N. Edwards, Prof. C. N. Hinshelwood (also representing the University of Oxford), Sir Thomas Holland (representing the Geological Society), Dr. J. S. Huxley, Sir Harold Spencer Jones (Astronomer Royal); Prof. E. A. Milne, Prof. N. F. Mott, Dr. Alex. Muir, Prof. R. G. W. Norrish, Dr. W. G. Ogg, Lord Radnor (representing the Rothamsted Experimental Station), Prof. E. K. Rideal, Sir Robert Robinson (representing the Royal Society of London), Prof. A. Sorsby (representing the Anglo-Soviet Medical Council), Prof. R. H. Tawney, Dr. Henry Thomas (representing the British Museum), Prof. D. M. S. Watson (also representing the British Association), Dr. W. A. Wooster (representing the Association of Scientific Workers).

James Alfred Ewing Medal

Award to Mr. B. N. Wallis

ON the joint recommendation of the presidents of the Royal Society and the Institution of Civil Engineers, the Council of the Institution of Civil Engineers has awarded the James Alfred Ewing Medal for 1944 to Mr. B. N. Wallis. The Medal is awarded annually for specially meritorious contributions to the science of engineering in the field of research. Mr. Wallis is chief of aeronautical research and development to Vickers-Armstrongs, Ltd. He invented and designed the special type of bomb used for the destruction of the Moehne and Eder Dams in Germany in 1943, and designed the Tallboy and 10-ton bombs used by the R. A. F. He was responsible for the design and construction of the airship *R. 100*. Since the airship programme was abandoned, he has been engaged in the design and development of geodetic construction to enable the production of long-range load-carrying aircraft, as exemplified in the production, in collaboration with Mr. R. K. Pierson, of the "Wellesley" type monoplane, which holds the world's non-stop record of 7,162 miles made in 1938. Geodetic construction has been used in the well-known "Wellington" bomber and the "Warwick".

Geology at Columbia University: Prof. S. J. Shand

PROF. S. J. SHAND has been appointed to fill the Newberry chair of geology at Columbia University. Shand, a graduate of the Universities of St. Andrews and Munster, spent a short time at the Royal Scottish Museum in Edinburgh, and then for twenty-five years was professor of geology at Stellenbosch. In 1937 he became professor of petrology in Columbia. He has devoted much attention to the occurrence and origin of the alkali rocks. He mapped masses of nepheline-bearing rocks in Sutherlandshire and the Bushveld, describing them in a series of masterly papers. As early as 1913 he was considering the thorny problems of the classification of eruptive rocks, and has recently elaborated one. In this the role of physical chemistry in helping to choose the diagnostic features of a rock is emphasized, and the result is practical and useful. A philosophical outlook permeates all he writes, and he has proved himself one of the most stimulating of living petrologists. Many geologists and others will be happy to learn of his promotion, and know he is a worthy successor to J. F. Kemp, C. P. Berkey and Douglas Johnson.

Industry and the University:

Exchange of Research Personnel

THE London, Midland and Scottish Railway has announced an important scheme whereby it will send members of its research staff for varying periods to carry out fundamental research in their particular fields in university laboratories, and, in exchange, the universities will be invited to send members of their staffs to spend a period in the company's research laboratory at Derby, working on applied problems in which they are interested from the fundamental side. The benefits should be felt by both parties to this arrangement. On one hand, it is hoped that the company's staff visiting the universities will be invited to assist in teaching, so bringing the practical atmosphere to the university lecture-room, on the other hand, university research men will be brought more closely into contact with the problems of industry. The L.M.S. Research Laboratory has a staff of seventy research workers, and has sections dealing with engineering, metallurgy, chemistry, physics, paint and textiles, hence it can provide a very varied experience for university research workers able to take advantage of the scheme. The company is to be congratulated on its foresight in promoting this exchange of research workers, it should prove an important step in promoting that two-way flow of research personnel between industry and the university, the need for which has been emphasized repeatedly in recent months. The example might well be followed in other industries.

Royal Asiatic Society of Bengal

IN the editorial article "Science and Progress in India" in *Nature* of May 5, p. 525, the history of the development of the present scientific background in India since the end of the eighteenth century is traced along two parallel lines of progress, official and non-official, the origin of the latter being the foundation of the Asiatic Society (now the Royal Asiatic Society of Bengal) by Sir William Jones in 1784. The annual address of Dr. Shyam Prasad Mookerjee, president of the Society for the year 1944-45, has now been received, as well as the annual report of the Council. It is pleasing that Dr. Mookerjee, the son of the late Sir Ashutosh Mookerjee,

one of the greatest presidents the Society has ever had, should have reached the presidential chair. An interesting point that emerges from Dr Mookerjee's address is that while official support was given to some aspects of science in India from as early a date as that of the birth of the Asiatic Society, the study of the cultural inheritance of India was left entirely to private non-official effort, both European and Indian, largely under the inspiration and encouragement of the Asiatic Society, until so late a date as 1860. In this year, during the time of Lord Canning, the first Viceroy of India, the Archaeological Survey of Northern India was constituted, while in 1862 Cunningham was appointed archaeological surveyor, to become later the first director-general of archaeology in India. After Cunningham came a period of stagnation until Lord Curzon reconstituted the Archaeological Department under Sir John Marshall. But the study of India's history as represented by ancient documents is still left to unofficial endeavour, organized mainly by the Asiatic Society, to which some official help is given in the form of annual grants towards the cost of study and publication.

Now that proposals are on foot for the expansion of scientific, medical and industrial research in India, the Asiatic Society, with its interests in all branches of learning—science and letters—does not propose to allow the cultural side of life to lag behind. For, as Dr Mookerjee says, "neither can India attain her full strength and glory nor can she contribute worthily to the cause of stabilizing human civilization, if we ignore the need for a proper cultural reconstruction in India." The Council of the Society, working through an advisory body formed for the purpose, has in consequence submitted to the Government of India during 1944 proposals on (1) the establishment of a Travellers' Department in India, (2) the necessity for a Central Record Office in Bengal, (3) the future development of the Archaeological Department, (4) the establishment of a National Museum at New Delhi as a war memorial, (5) the amendment of the Ancient Monuments Preservation Act, (6) the establishment of a School of Architecture in India, (7) the necessity for a National Cultural Trust, (8) the establishment of a National Academy of Art and Letters, (9) the constitution of national parks. These projects are for the future. As a useful activity for the present the Society has organized a series of discussion meetings to which invitations have been extended to all members of the Allied Forces in Calcutta. No less than thirty-nine meetings were held during 1944, addressed by a variety of lecturers on historical, literary, economic, industrial, and scientific subjects. The British and American military authorities co-operated in making these meetings a success, the one by a contribution towards the expenses, and the other by gifts of materials for providing refreshments. The Asiatic Society of Bengal proposes next year to celebrate the bi-centenary of the birth of its founder, Sir William Jones.

Astronomy in France during the Occupation

In the February issue of *The Observatory* (66, 23, 1945), D. Chalonge gives a brief history of French astronomy and astronomers during the German occupation. Among the astronomers dismissed under the Vichy racial decrees—M. Lambert, director of the Bureau International de l'Heure, M. Mendès, M. Beloritzsky and Mlle Bloch, assistants at the

Observatories of Bordeaux, Marseilles and Lyons respectively—all have been reinstated except M. Lambert, who was arrested in August 1943 and deported to Germany, and about whose safety there is anxiety. M. Meneur, director of the Institut d'Astrophysique, was several times imprisoned for political reasons. Removed by the Vichy Government from his post at the Observatory of Paris, he devoted much of his time to the resistance movement, and is now back with his former colleagues. M. Danjon, director of the Observatory of Strasbourg and dean of the Faculty of Science in the University, was also many times arrested by the Germans during the Gestapo campaign against the University, and was finally dismissed by the Vichy Government. Many astronomers were, however, allowed to work in the tranquillity of their observatories. In some cases this tranquillity covered patriotic activities, the observatories becoming meeting-places for the local resistance groups where pamphlets were printed and arms stored. Observatory buildings throughout France have come through the War unscathed, except perhaps those at Strasbourg, about which news is still lacking.

Development of the Service d'Astrophysique, founded in 1936, was interrupted by the outbreak of war. The Institut d'Astrophysique buildings in Paris were finished externally in 1940 when the Germans forbade further work, but this edict was clandestinely evaded with such success that workshops and laboratories were ready for use by January 1944. At the Observatory of Haute Provence, which forms part of the Service d'Astrophysique, many of the projected buildings were completed, and a 120-cm telescope was brought into use a year ago. An 80-cm telescope will shortly be installed in a dome already awaiting it. Work has continued on the Pic du Midi, where Lyot has carried on his researches on the solar corona outside eclipse and on planetary surface detail. Other researches published or to be published in the *Annales d'Astrophysique* include work on the night sky spectrum, photometric and spectrophotometric studies of lunar eclipses, investigations, observational and theoretical, on the continuous spectra of stars and diffuse nebulae, observations of total hydrogen absorption in certain stellar spectra, and a study of the monochromatic brightness across the sun's disk.

Public Health in San Salvador

An article on this subject appears in the February issue of the *Boletín de la Oficina Sanitaria Pan-americana* by Dr Manuel Zúñiga Idíáquez, head of the Department of Health Education of the El Salvador Ministry of Health. San Salvador's public health organization traces its origin to the Superior Board of Health at the beginning of this century, which was succeeded in 1920 by the National Department of Health. Since then much progress has been made as regards the preventive, rather than the curative, side of public health and the training of staff. The Rockefeller Foundation and the Pan-American Sanitary Bureau have been of great help, especially as regards the formation of a body of specialists in public health. At the present time valuable aid is also being received from the Co-operative Inter-American Public Health Service, permitting the installation of safe water and sewage disposal systems, malaria control work, sanitary materials, public laundries and new buildings and health centres.

Medical Research in Sweden

A COMMITTEE of Swedish experts has drawn up plans for the establishment of a Central Council for Medical Research, and the granting of yearly allocations of Kr. 1,000,000 for medical research. The committee recommends that the annual sum of Kr. 400,000 should be granted for medical research at the Universities of Uppsala and Lund, the Caroline, Dental and Veterinary Institutes, and that Kr. 600,000 should be put at the disposal of the Council. As projected, the sum of Kr. 400,000 is to be divided among the five university colleges every year. Further, the sum of Kr. 135,000 would be used for bursaries of Kr. 5,000 each for students' courses on medical and related subjects. The Council could, among other things, have the task of organizing collaboration between scientific men working on research in natural science and medicine.

Summer School in Social Biology

At the Summer School in Social Biology which the British Social Hygiene Council (Tavistock House North, Tavistock Square, London, W.C.1) will be holding at University College, Nottingham, during July 28–August 11, interest will be directed chiefly to problems of education and social life likely to arise through the coming increase in the school-leaving age. The director of the School will be Prof. Winifred Cullis. The School is open to teachers, social workers and members of the general public interested in education and social problems from a biological angle. The morning lecture programme has been planned to illustrate the aims and content of social biology. Tea-time discussions will be reserved for subjects concerned with actual classroom problems of teaching social biology. In addition, an elementary course in the dissection of certain animal types will be available for those teachers who make special application. At the evening sessions lectures will be given by a distinguished group of visiting speakers on the broader application of biological knowledge to human life and culture. Acceptances to speak have been received from Prof. T. H. Morgan, Sir Drummond Shiels, Dr. Otto May, Father Cyster King, Dr. Glover and Dr. David Mace. One special feature of the Summer School will be the Sunday sessions, at which lectures and discussions will be held upon the relation of biological science to "higher values and spiritual life". Further information about the School can be obtained from the secretary, British Social Hygiene Council, Tavistock House North, Tavistock Square, London, W.C.1.

South-Eastern Union of Scientific Societies

THE fiftieth annual congress of the South-Eastern Union of Scientific Societies will be held this year on July 7 at Harpenden, the headquarters being at the Rothamsted Experimental Station. The president-elect is Dr. W. G. Ogg, who will speak on some aspects of the work at Rothamsted, of which he is rector. The sectional presidents and their addresses are: Mr. Edward Yates (archæology), "Church Halls"; Dr. W. E. Brenchley (botany), "Trace Elements"; Mr. P. Evans (geology), "Some New Weapons in the Geological Armoury"; Dr. C. S. Elwin (social science), "Country Planning"; Dr. S. Russell (zoology), "Fishing Research and the Overfishing Problem". The honorary general secretaries of the Union are Mr. A. Farquharson and Mr. J. Epps, 78 Dunwich Road, Bexley Heath.

University of London Appointments

DR. A. B. HILL, since 1933 University reader in epidemiology and vital statistics at the London School of Hygiene and Tropical Medicine, has been appointed to the University chair of medical statistics tenable at the School, as from October 1. During 1939–42 Dr. Hill was in charge of the Statistical Section in the Research and Experimental Department of the Ministry of Home Security, and since 1934 he has served part-time on the staff of the Medical Directorate of the Royal Air Force and was appointed consultant in medical statistics to the Royal Air Force.

Dr. Karl R. Popper, since 1937 senior lecturer in philosophy at Canterbury College, New Zealand, has been appointed to the readership in logic and scientific method tenable at the London School of Economics, as from October 1.

The title of reader in organic chemistry in the University of London has been conferred, as from October 1, on Dr. E. R. H. Jones, in respect of the post held by him at the Imperial College of Science and Technology.

Television—Past and Future

IN the account in *Nature* of May 26 of an address by Mr. H. L. Kirke, the statement is made (p. 622) that a mobile transmitter was "developed by the B.B.C." for supplying outside broadcast television features. Mr. Kirke writes stating that the script of his lecture read: "the pioneer development work in the use of Post Office cables in this way was done by the B.B.C.". He adds, "the development of the mobile transmitter was undertaken by Messrs. E.M.I., although I did not actually mention this in my lecture or in the script."

Announcements

SIR PEIRSON FRANK, chief engineer of the London County Council, has been elected president of the Institution of Civil Engineers for 1945–46.

At the annual general meeting of the Institute of Physics, held on June 4, the following were elected to take office on October 1, 1945: *President*, Sir Frank Smith; *Vice-President*, Prof. A. M. Tyndall; *Honorary Treasurer*, Major C. E. S. Phillips; *Honorary Secretary*, Prof. J. A. Crowther; *Ordinary Members of the Board*, Dr. B. P. Dudding, Mr. A. J. Maddock, Prof. W. Sucksmith and Dr. C. Sykes. Prof. C. T. R. Wilson was elected an honorary fellow of the Institute.

MESSRS. NEWTON CHAMBERS AND CO., LTD., are providing the South Yorkshire Section of the Royal Institute of Chemistry with a sum of £100 per annum for five years for the award of an annual prize for contributions to the subject of chemistry and industrial welfare. The 1945 competition is open to any fellow, associate or registered student of the Institute who had not reached his thirty-sixth birthday by January 1, 1945, and the award is offered for an essay, paper or papers, published or unpublished, embodying the candidate's own observations, or experimental work, on some aspects of the application of chemistry to the promotion of industrial welfare. A critical examination of existing knowledge is admissible, provided that the conclusions reached constitute an addition to the knowledge of the subject. Papers must reach the honorary secretary of the South Yorkshire Section, Royal Institute of Chemistry, c/o Newton Chambers and Co., Ltd., Thorncliffe Works, Sheffield, by December 31, 1945.

Dirac's Equation for the Neutron and Proton

In the attempt to discover a place for Dirac's equation in the geometry and metric of the physical world, it has been proposed to make use of Weyl's concept of gauging. It was thus proposed to bring about the union of gravitation and electromagnetism by Kaluza's suggestion of the adoption of a five-dimensional continuum leaving the idea of gauging free to bring about the union of the quantum theory with these branches of physics.

In order to carry out this idea, it was found necessary to introduce the concept of matrix-length and to apply a parallel displacement to it. A gauging factor, ψ , was introduced which was identified with the ψ of Dirac's equation. The result of the argument was the equation

$$\gamma^\mu \frac{\partial \psi}{\partial x^\mu} = 0,$$

as the condition that there should be no change in length in a parallel displacement. In this equation the matrices (γ^μ) are five in number and are readily related to the familiar Dirac matrices. The equation can be regarded as a gauging equation and is identical with Dirac's equation¹.

In the original work the equation was more general and can be expressed in the form:

$$\gamma^\mu \frac{\partial \psi}{\partial x^\mu} = H_\mu \gamma^\mu \psi.$$

This is the result of a close analogy with the idea of Weyl that a change of length occurs with a parallel displacement, and in place of the electromagnetic potential (ϕ_μ), the operator (H_μ) occurs. It appeared from the identity of the equation, which resulted from placing $H_\mu = 0$, with Dirac's equation that the purpose of incorporating Dirac's equation in a natural way into physical theory was achieved by this simple condition. But the development of the theory of the nuclear field has shown that it bears to the five-dimensional framework a relation similar to that which exists between the electromagnetic theory and gravitation². Thus it would be natural to drop the simple equation $H_\mu = 0$ when a nuclear field exists. If we can decide upon the correct expression for H_μ in this case, the result should lead to Dirac's equation for the neutron and proton.

Following Weyl, it would be expected that H_μ depended linearly upon the potential components, usually denoted by U_μ . But in the five-dimensional theory these are the components, ($T_{\mu\nu}$), of the tensor of the nuclear field in which the suffix 5 appears. Thus it is in the interest of generality to express H_μ linearly in terms of the components, $T_{\mu\nu}$.

The simplest operator form is that which results from combining the matrices (γ^μ) with ($T_{\mu\nu}$) in order to produce a covariant quantity H_μ . At the same time it is necessary to include the matrices $\tau = \begin{pmatrix} 00 \\ 10 \end{pmatrix}$

and $\tau^* = \begin{pmatrix} 01 \\ 00 \end{pmatrix}$ to account for the neutron-proton interchange. Thus the simplest form is $H_\mu =$

$g\gamma^\nu(T_{\mu\nu}\tau + T_{\mu\nu}^*\tau^*)$, where g is a constant, and where as usual in the field theory we combine $T_{\mu\nu}$ and its conjugate complex quantity. Thus the proposed quantum equation for the neutron and proton

$$\gamma^\mu \frac{\partial \psi}{\partial x^\mu} = g\gamma^\nu \gamma^\mu (T_{\mu\nu}\tau + T_{\mu\nu}^*\tau^*) \psi.$$

This equation appears in a paper by H. J. Bhabha in which he develops equations for the nuclear field by the Hamiltonian method. A characteristic feature of the form of the equation developed here is the appearance of one constant, g , only. In other presentations the field is characterized by the appearance of two constants, g_1 and g_2 . It would appear from the equation that $g_1/g_2 = 2\pi M_0 c/h$, where M_0 is the mass of the particle emitted in the neutron-proton interchange. This agrees with the five-dimensional formulation of the nuclear theory⁴.

Coloured Haloes Surrounding Inclusions of Monazite in Quartz

QUARTZ crystals with zonal colour from the Transbaikalian region were found with inclusions of monazite crystals (diameter 0.1–1.0 mm.) around which the quartz was of an intense smoky colour. The coloration, more intense at the centre, shaded off gradually towards the periphery of the halo. Although the boundaries of the halo were not sharp, yet they were sufficiently distinct to enable measurements of the halo to be made (Fig. 1). Haloes of all dimensions from 0.5 mm. to 5–6 mm. diameter can be found in the same quartz specimen.

The formation of these spherical haloes can be attributed to the corresponding radioactive emanations (β or γ). Calculations have shown that haloes of such dimensions and with sufficiently well-marked boundaries could be produced by the action on quartz of hard β -rays (in quartz $\mu \approx 10 \text{ cm.}^{-1}$) spreading

Fig. 1. $\times$ about 7.

Fig 2

om the monazite and presumably emanating from sintegration products of thorium contained in onazite. These spherical haloes in quartz are the first clearly observed natural colouring action of rays, and can be called β -haloes to distinguish them from the well-known concentric α -haloes.

For haloes of the same geological age (in the same quartz specimen), the radius r of the inclusion can be related, as a first approximation, to the radius R of the halo by the equation $r = \sqrt[3]{kR^2e\mu R}$, confirmed by observation (Fig 2).

With geological ageing, owing to accumulation of the pigment, the boundaries of the halo gradually extend. After comparing the action on a given specimen of a standard preparation to determine the constant k , an attempt can be made to determine approximately, from the length of the radius of the halo, the time necessary for the production of a just perceptible coloration in the quartz, at a given distance from a source of given intensity. The formula $t \approx \tau \ln [(k^2 Q_0^{-1} R^2 e \mu R) + 1]$, where $\tau = 1/\lambda$ is coefficient of disintegration) enables such calculations to be made.

In addition to the intensity of the source of radiation and the time of action, the radius of the β -halo depends also on the power of the given medium to colour, that is, the degree of its sensitivity (due possibly to presence of Fe). Thus sometimes, far beyond the boundaries of the halo itself, in the more sensitized layers of the quartz crystal, traces of the action of the radiation can be observed as coloured streaks.

By artificial action of, say, X-rays, the whole crystal becomes coloured and layers of more intense colour appear which were not apparent before. Previously only those layers of quartz were coloured, considerably fainter than the haloes, which were formed at a time when monazite crystals were being deposited. The quartz presumably adsorbed from

solution the sensitizing as well as the active admixture. This occurred in periods of growth following periods of rest or even re-solution of the crystal due to external phenomena, indicated by the rounding of zones at the apexes and edges of the crystal below the coloured zones where inclusions of monazite with surrounding β -haloes are found.

Chromatography of Two Solutes

THE complete theory for the chromatography of a single solute has been given recently^{1,2}, but the general case of two or more solutes has not yet been solved^{3,4}.

We consider the problem for two solutes I and II, where the amounts adsorbed are given by the respective adsorption isotherms

$$q_1 = f(c_1, c_2) \quad , \quad q_2 = g(c_1, c_2).$$

There is no need to assume a specific form for f and g , but we shall suppose, what is almost certain to be the case, that they are regular functions of c_1 and c_2 for small c_1 and c_2 .

It is well known that the following differential equations are satisfied

$$\frac{\partial c_1}{\partial x} + \frac{\partial f}{\partial v} = 0 \quad , \quad \frac{\partial c_2}{\partial x} + \frac{\partial g}{\partial v} = 0. \quad (1)$$

One can show that under normal initial conditions c_1 and c_2 are functions of v/x . However, sometimes in the subsequent development of the bands with pure solvent this may cease to be true.

Writing $y = \frac{v}{x}$, we can show that either $\frac{dc_1}{dy} =$

$\frac{dc_2}{dy} = 0$ which implies that c_1 and c_2 are constants, or

$$\frac{df}{dc_1} = \frac{dg}{dc_2} = y, \quad (2)$$

from which we deduce that

$$\frac{dc_1}{dc_2} = \frac{2f'c_2}{(g'c_2 - f'c_1)} \left\{ 1 + \sqrt{1 + \frac{4f'c_2 g'c_1}{(g'c_2 - f'c_1)^2}} \right\}^{-1}.$$

This equation determines c_1 as a function of c_2 , and then each can be obtained as a function of (v/x) from the relation

$$\frac{v}{x} = f'c_1 + \frac{2f'c_2 g'c_1}{(f'c_1 - g'c_2)} \times \left\{ 1 + \sqrt{1 + \frac{4f'c_2 g'c_1}{(g'c_2 - f'c_1)^2}} \right\}^{-1} \quad (3)$$

It has been shown already by Wilson³ and de Vault⁴ that if a chromatogram is made from a solution of two substances, the normal result is to obtain a band in which the two solutes I and II are mixed in constant proportions determined by the original concentrations, and then below this a band containing only one of the solutes with a uniform distribution determined by the original concentrations.

If the original concentrations do not differ greatly, then the lower band will usually contain the solute which is the less strongly adsorbed. However, if the concentration of one solute is small compared with the other, then the lower band may very likely contain the more concentrated even when it is the more strongly adsorbed component. For convenience of expression, we shall always suppose that the lower band consists of solute II.

When we develop the chromatogram with pure solvent, both bands move down the tube and a third band is formed at the top. This new band consists of solute I if

$$(f'c_1)c_1=0 > (g'c_2)c_2=0, \quad (4)$$

and of solute II if the inequality opposite to (4) is satisfied. The resulting chromatogram will normally consist of a band of solute I of varying concentration, a band of a mixture of solute I and II, and below this a band of solute II. However, if the original concentration of the solute I is small compared with that of II, and if the opposite inequality to (4) is satisfied, then we may have a band of II, a mixed band and then a band of solute II again and no free solute I.

Let us suppose that the inequality (4) is satisfied. The top edge of the band of solute I after development with a volume v of pure solvent will then be given by

$$\frac{v}{x} = (f'c_1)c_1=0; \quad (5)$$

and the top edge of the band consisting of a mixture of solutes I and II by the simultaneous equations

$$\frac{v}{x} = (f'c_1)c_2=0 = (g'c_2)c_2=0$$

This enables us to estimate the amount of solute I set free by development with a given volume of pure solvent and the volume of pure solvent required to separate completely the two solutes. If $F(c_1) = f(c_1, 0)$ and if c'_1 is determined by

$$F'(c'_1) = [g'c_2(c'_1, c_2)]_{c_2=0}, \quad (6)$$

then the amount of pure solute I after development with volume v will be

$$v \left\{ \frac{F(c'_1)}{F'(c'_1)} - c'_1 \right\}$$

If the original chromatogram was formed from a volume v_0 of the solutes I and II, then the volume v of pure solvent required to separate completely the solutes is given by

$$v \left\{ \frac{F(c'_1)}{F'(c'_1)} - c'_1 \right\} = v_0 c_1^0, \quad (7)$$

where c'_1 is given by (6) and c_1^0 is the original concentration of solute I.

A full account of the theory will be published elsewhere, and related experimental work is in progress.

Absorption of Cosmic Rays at Colombo and London

Using the standard form of G.M. counter telescope of Fig 1, we have made a comparison of the absorption of the vertical component in lead at sea-level, in London and a Colombo, the only difference between the two sets of apparatus being that, at Colombo, the top counter was missing. The results are given in Figs 2 and 3, the deviations shown being standard deviations, and the following values are found for the percentage soft component and absorption coefficient of the hard component

	Soft component (% of total)	Mass absorption coefficient hard component
London	29 ± 0.7	$5.1 \times 10^{-4} \text{ cm}^2/\text{gm}$
Colombo	23 ± 1	$5.1 \times 10^{-4} \text{ cm}^2/\text{gm}$

A plateau was found on both curves for thicknesses greater than 10 cm (that is, after complete absorption of the soft component), the significance of this will be more fully discussed elsewhere. This is where the hard component is produced back to zero thickness as shown in the dotted lines.

Fig 2

Fig 3

The absorption coefficient of the meson or hard component is found to be the same in both places and agrees with that found by other workers¹, but there is a significant drop in the percentage of the electronic or soft component at Colombo.

Ultimate Vacuum Attainable by a Diffusion Pump

THE following experiments were recently performed to see the nature of pumping action inside a diffusion pump and to throw some light on the controversial question of the ultimate vacuum attainable by a diffusion pump.

While Gaede¹ and Langmuir² held that there is theoretically no limit to the vacuum produced by diffusion pump, Hickman^{3,4} reported that the limit of pumping is set at the vapour pressure of the pump fluid at room temperatures, and he devised the 'self-fractionating' oil-diffusion pump which is capable of producing higher vacuum. Newman⁵ believed that the pumping action would cease when the partial pressure of air, contained in the jet vapour as contamination, equals the pressure in the vessel.

Table 1 shows the pressure gradient down the barrel of an orthodox oil-diffusion pump with single umbrella-type jet, all brass and 4-in. in diameter. Tappings of nozzles were taken from seven different positions relative to the vapour jet, and could be connected to vacuum gauges. The pump was charged with Apiezon oil B, and had been in use for a few weeks.

A rubberless McLeod gauge was used for reading the pressure and also for calibrating a Pirani gauge. The Pirani gauge was calibrated across a liquid oxygen trap, so that without the trap the Pirani reads the total pressure (partials of air and vapour), as contrasted with a McLeod gauge which reads air pressure only. Table 2 shows the vacuum (partial and total) obtained by a three-stage mercury diffusion pump without a cold trap.

It is brought out clearly by the experiments that a diffusion pump can reduce the partial pressure of air far below the vapour pressure of the fluid, and as long as the pump is running, the vessel is not filled with the fluid vapour up to its saturation value for the room temperature. The partial pressure of air contamination of the jet will, similarly, not manifest itself fully in the vessel.

The successful functioning of a diffusion pump is apparently vitally dependent on the streamline issue of the jet vapour, and the small differences of vapour pressure of the fluid are not likely to affect the vacuum to any great extent. A perfect streamline flow of the jet vapour directed away from the diffusion aperture (neck) would cause only the fusing out of the air (or vapour, etc.) from the vessel into the jet stream, where the molecules would

0.02	0.50	0.48	2.0	0.24

be caught by the forward stream of vapour and knocked on towards the backing pump, and would lead theoretically to perfect vacuum with time.

The practical vacuum, however, would depend upon the degree of back-streaming at the jet for several reasons, chiefly, the imperfection of the jet design, and the turbulence and pressure condition below the jet. The back-diffusion consists of vapour (easy to freeze out) as well as air. The latter (air) comes from the contaminated fluid from the boiler where the fluid returns through the air-laden column at the lower ('compression') part of the diffusion pump barrel. The turbulent condition set up by the abrupt rise of pressure below the single jet is also responsible for the back-escape.

The process of 'self-fractionation', originated by Hickman, not only helps in grading out the degenerated fractions of the oil but also helps very much in freeing oils of the inner compartments from air contamination. The inclusion of a number of jets in the fractionating pump also helps in getting more perfect streamline flow of vapour at the upper jets. This picture accords well with the success of a fractionating oil diffusion pump without laying too much stress on the vapour pressure of pump fluid, as demanded by the diffusion theory and the present experimental evidence.

Work is in progress and the details will be published elsewhere.

Our thanks are due to Prof M. N. Saha for his keen interest in the work. Our thanks are also due to Mr J. R. Basu Mallick, for designing the tappings and getting the oil diffusion pump constructed for the purpose. We also acknowledge our thanks to the authorities of the Board of Scientific and Industrial Research for kindly permitting the work to be published.

Codecarboxylase Function of 'Pyridoxal Phosphate'

Six specific amino-acid decarboxylases have now been obtained in a cell-free state from various bacteria^{1,2,3,4}. Of these, the enzymes decarboxylating *l*(+)-lysine, *l*(-)-tyrosine, *l*(+)-arginine and *l*(+)-ornithine have been resolved into apoenzyme moieties activated by the presence of a common codecarboxylase of which a concentrate has been prepared from yeast⁵. The remaining enzymes,

specific for *l*(-)-histidine and for *l*(+)-glutamic acid, have not been resolved and appear not to contain codecarboxylase. The four codecarboxylase enzymes are highly sensitive to cyanide, hydrazine, hydroxylamine and semicarbazide, suggesting that a keto-group is involved in their action⁴.

Strains of *S. faecalis* which possess tyrosine decarboxylase are unable to produce the enzyme when grown in a simplified medium⁶, the active enzyme being formed only if the medium contains amounts of nicotinic acid and pyridoxin in excess of simple growth requirements⁷. Organisms grown in pyridoxin-deficient media are almost inactive towards tyrosine but can be activated by the addition of pyridoxal to the suspensions⁸; if the cells are dried, then pyridoxal is active in the presence of adenosinetriphosphate but inactive alone⁹. In the latter case an active substance can be obtained by treating pyridoxal with thionyl chloride followed by silver dihydrogen phosphate or with phosphoric acid alone⁹. Pyridoxal and pyridoxamine act as the 'pseudo-pyridoxin' growth-factor for *S. lactis* R.¹⁰

EFFECT OF 'PYRIDOXAL PHOSPHATE' CONCENTRATION ON RATE OF DECARBOXYLATION OF *l*(-)-TYROSINE BY TYROSINE APO-DECARBOXYLASE (●-●) OF *l*(+)-LYSINE BY LYSINE APO-DECARBOXYLASE (○-○)
Manometer cups contain 0.3 ml apo enzyme preparation, 0.5 ml *M*/15 tyrosine or lysine, 1.5 ml *M*/5 acetate buffer pH 5.5 (tyrosine enzyme) or *M*/5 phosphate buffer pH 6.0 (lysine enzyme), water/'pyridoxal phosphate' preparation to 1.0 ml
Temperature = 30°C

We have now tested the codecarboxylase activity of 'pyridoxal phosphate' with the apo-decarboxylases specific for lysine, tyrosine, arginine and ornithine prepared and tested under optimal conditions as previously described^{1,2,4}. We obtained pyridoxal in about 20 per cent yield by oxidation of pyridoxin with neutral potassium permanganate under conditions similar to those described by Harris, Heyl and Folkers¹¹. The 2,4-dinitrophenylsemicarbazone was prepared, mp 212° (found C, 46.1, H, 4.0, C₁₅H₁₄N₄O₇, requires C, 46.2, H, 3.6 per cent). Pyridoxal was inactive as codecarboxylase when tested against tyrosine apo-decarboxylase but was activated if incubated in the presence of the enzyme preparation and adenosinetriphosphate. Before phosphorylation, pyridoxal was purified through the oxime and acetal, and the hydrochloride of the aldehyde then refluxed for five minutes with an excess of thionyl chloride before standing overnight. Excess reagent was removed *in vacuo* and the product shaken with a suspension of silver dihydrogen phosphate in glacial acetic acid for 24 hours. Filtration followed by removal of acetic acid *in vacuo* left a resin. This was dissolved in water and silver ions

removed by addition of dilute hydrochloric acid. The preparation was preserved as the lead salt.

TABLE 1 CODECARBOXYLASE ACTION OF 'PYRIDOXAL PHOSPHATE' Activities estimated manometrically, as previously described^{1,2}

Apo-enzyme	Alone	+ excess codecarboxylase	+ excess 'pyridoxal phosphate'
<i>l</i> (-)-Tyrosine decarboxylase	2	110	116
<i>l</i> (+)-Lysine decarboxylase	15	108	104
<i>l</i> (+)-Arginine decarboxylase	15	70	75
<i>l</i> (+)-Ornithine decarboxylase	29	78	74

Table 1 shows that the preparation is active as codecarboxylase for the four enzymes, and the accompanying figure shows the shape of the curves obtained by adding increasing amounts of the preparation to a given amount of the apo-enzymes of lysine and tyrosine decarboxylases and measuring the resulting decarboxylase activities. Codecarboxylase from yeast is stable to mild alkaline hydrolysis and unstable to acid⁵, table 2 shows that the active material in the 'pyridoxal phosphate' preparation has similar stabilities. Proof of the identity of the synthetic and natural products must await their isolation in a pure state; the concentrate of natural product was stated formerly to be phosphate-free (Weiler)⁵, but this has now been submitted to re-analysis and proves to contain 0.8-1.0 per cent (Roche). Assuming that the dissociation constant for the tyrosine apo-decarboxylase-coenzyme complex is of the same order as that determined indirectly for pyridoxal using inactive whole organism⁸, it is possible to calculate the approximate yield of 'pyridoxal phosphate' from the curve for the recombination of tyrosine decarboxylase in two preparations; the yield of 'pyridoxal phosphate' calculated on this basis represents approximately 0.1 per cent of the pyridoxin used.

TABLE 2 STABILITIES TO ACID AND ALKALI OF CODECARBOXYLASE AND 'PYRIDOXAL PHOSPHATE' Activities expressed as units codecarboxylase/ml preparation estimated against tyrosine apo-decarboxylase⁵

Treatment	Codecarboxylase Units/ml	'Pyridoxal phosphate' Units/ml
Initial (untreated)	32	23
After 1 hr at 100°C		
(a) in 0.1 <i>N</i> NaOH	31	24
(b) in <i>N</i> NaOH	31	20
(c) in 0.1 <i>N</i> H ₂ SO ₄	11	7

Failing the isolation of the active substance in pure state, it is not possible to assign a formula to it with certainty, but from the nature of the reaction described above, it seems probable that 'pyridoxal phosphate' bears a phosphoryl residue on the primary hydroxyl group of pyridoxal.

Effect of Change of Coat on the Growth of Epidermal Warts in Mice

THE paper on the artificial production of coat colour in the albino rat by Haddow and others¹ throws light upon some observations, recently made, on the growth of epidermal tumours in mice in relation to the growth of the nearby hair. The results had already been written up and are as follows.

It is well known that epidermal warts in mice produced by painting with tumour-producing agents show periods when their growth-rate is reduced, their size diminished, or they may even temporarily disappear. Having occasion to observe the growth of hair near warts for other purposes, it was noted that diminution in growth of the warts occurred when in black mice the surrounding skin, normally pale, became pigmented as it does when the hair bulbs are enlarging preparatory to the formation of new coat. In white and pale-coloured mice, this early growth of the hair bulbs cannot be seen, and the onset of a new coat shows itself later by the appearance of new hair.

The correlation between pigmentation of the skin in black mice and diminished growth of the warts is shown in Fig 1.

Fig 1 THE FIGURE SHOWS THE SUPERFICIAL DIMENSIONS (MAJOR AND MINOR AXES) OF EPIDERMAL WARTS IN BLACK MICE, PRODUCED BY PAINTING WITH BENZOPYRENE, PLOTTED AGAINST TIME. DOTTED LINES INDICATE TIMES WHEN THE SKIN AROUND THE WARTS WAS UNPIGMENTED AND FULL LINES WHEN IT WAS PIGMENTED. THE NUMBERS ON THE LINES GIVE THE AREA OF THE WARTS IN SQ. MM.

Times of pigmentation are clearly associated with arrested growth of the warts. Bleeding (B) and necrosis (U) of the warts also have this effect (see warts E and I). Wart H disappeared for a short time at O. The periods of pigmentation are about a week in duration.

Many warts are of a full pink colour during life, as soon as the surrounding skin became pigmented, it was noticed that they changed from pink to white or bluish-white, suggesting that their blood supply had been greatly reduced. Sections were therefore made of the skins of black mice in various stages of hair growth, and it was found that the capillaries surrounding the hair bulbs were widely distended with blood when they were actively growing. When forming pigment at the same time, it was found that the capillaries of the dermal papillae were

much less in evidence than in skins in which the hair bulbs were quiescent.

The conclusion was drawn that the growing hair bulbs caused a diversion of blood to them and away from the overlying epidermis and warts, hence their blanching, their lowered growth-rate and diminution in size.

If a rosy and a blanched wart be ligatured during life, fixed and sectioned, there is seen a great difference in the extent to which the capillaries and venules are distended with blood, sufficient to account for the considerable diminution in size and the complete flattening out of small warts.

The number of mitoses in the epidermis was counted before, during and after hair growth, and it was found that the number was greatly reduced during the time when the hair bulbs were actively growing. Details of these findings are given in Fig 2.

Fig 2 THE FIGURE SHOWS THE NUMBER OF METAPHASES PER 100 MM. OF SECTIONS OF SKIN 7 μ THICK ON DAYS BEFORE, DURING AND AFTER PIGMENTATION OF THE SKIN (P) IN PREPARATION FOR A CHANGE OF COAT. ALL SPECIMENS WERE TAKEN AT 10 A.M. TO AVOID DIURNAL VARIATION. THE BLACK BLOCK INDICATES THE DURATION OF PIGMENTATION.

This inhibition of mitosis is presumably the result of the lessened blood supply to the epidermis. Though a lowered rate of mitosis can account for the warts growing more slowly, it cannot account for their diminution in size as can the collapse of blood vessels.

Thus was independently observed the close correlation between hair growth and dilatation of the local capillaries, described by Haddow. He suggests that variation in blood supply controls hair growth, but it may be the reverse, that hair follicles stimulated to grow call forth capillary dilatation. In either case, secondary effects follow a diminution of blood supply to the epidermis and a temporary lowering of epidermal cell division.

The way in which new coats of hair spread gradually across the skin, as described by Haddow, for the rat, was also seen in the mouse. In the mouse there is a lateral line down the flank, well seen in black and tan mice, along which new coats of hair start and spread either dorsally or ventrally, not both ways.

at any one time. When mice are painted on the flanks with single applications of benzpyrene, the yield of tumours is affected by the condition of the hair at the time of painting, but because the spread of the new coat is very easily disturbed, for example, by plucking the hair or even by clipping it, controlled conditions are difficult to maintain. This confirms Haddow's finding that coat change is easily disturbed.

Synthesis of the Differential Growth Inhibitor, δ -Hexenolactone

Two years ago, Medawar, Robinson and Robinson¹ described the isolation from a commercial malt extract of small quantities of a steam-volatile substance which inhibited the growth of fibroblasts and other mesenchyme cells at concentrations which permitted the free growth of epithelial tissue. It seemed probable that this material was an unsaturated lactone, $C_6H_8O_2$, and it was found that synthetic specimens of *dl*- δ - $\Delta^{\alpha\beta}$ -hexenolactone (III) (the *d*-form of which occurs in the fruit of the mountain ash) exhibited similar inhibitory properties, although the activity was rather less than that of the natural inhibitor. The differential growth-inhibitory properties of this lactone have since been confirmed by other workers².

The *dl*-lactone (III) was synthesized in small yield by Medawar, Robinson and Robinson by condensation of acetaldehyde with malonic acid in pyridine solution, and Kuhn and Jerchel³ obtained it from β - δ -dibromocaproic acid by boiling with water, the overall yield from sorbic acid being about 25 per cent. We have now found that the lactone can be prepared readily as follows:

Condensation of propylene oxide with sodium acetylidyde in liquid ammonia gives the carbinol (I) in 50 per cent yield. Treatment of the carbinol with two equivalents of ethylmagnesium bromide followed by carboxylation with carbon dioxide under pressure results in a 75 per cent yield of the crystalline hydroxy-acetylenic acid (II), m.p. 59°, which on semihydrogenation employing a 0.3 per cent palladium-barium sulphate catalyst gives *dl*- δ - $\Delta^{\alpha\beta}$ -hexenolactone directly, as a colourless stable oil, the overall yield from propylene oxide being about 35 per cent. The constants of the lactone are in agreement with those recorded by Kuhn and Jerchel³, and it exhibits the expected growth-inhibitory action*.

* We are indebted to Sir Robert Robinson and Dr Medawar for a report on the inhibitory properties.

This synthesis has the advantage of being readily adaptable to the preparation of related lactones, and these lines are being actively pursued.

Metabolism of Quinine in Chick Livers

In a recent paper Oldham, Kelsey, Cantrell and Geiling¹ reported that in White Leghorn chicks doses with quinine the concentrations of alkaloid in tissues were lower in young chicks than in grown birds. They suggested that quinine was metabolized more rapidly in chicks than in older birds. *In vivo* experiments by these workers on the quinine oxidase activity of the tissues, however, failed to show any activity in the liver, and showed only very slight activity in the kidney.

In similar experiments on quinine oxidase activity we have been able consistently to demonstrate definite activity in chick livers (strain Rhode Island Red $\times$ Light Sussex). Moreover, the activity increased with increasing age, as shown in the accompanying table. Chick embryo livers and whole embryos show a very high activity.

Material	Mean quantity of quinine (micrograms) metabolized in 2 hours by 0.5 gm. tissue
Whole embryo (10 day) (wt. unknown)	7.0
Embryo liver (10 day)	216
" (20 day)	154
Chick (1 day old)	87
" (1 week old)	97
" (2 weeks old)	69
" (4 weeks old)	94
Chicken (8 weeks old)	53
" (17 weeks old)	45
" (26 weeks old)	19
" (3 years old)	26

The discrepancy between our observations and those of Oldham *et al.* might be partly due to the fact that we used the phosphate buffered salt solution of Krebs and Henseleit² instead of ordinary Ringer-Locke solution, and also raised the temperature of incubation to 40° C to correspond with the body temperature of the birds. In one experiment on the liver from a three-week-old chick in Ringer-Locke, only micrograms of quinine were metabolized. Other causes of the difference of results might be differences in the strain of birds used, or dietary variations. We have in some cases experienced large variations in the quinine oxidase activity among birds of similar age.

Meiosis in Tropical *Rhoeo discolor*

MEIOSIS in *Rhoeo discolor* growing under temperate conditions has been described by Bhaduri¹, Darlington^{2,3}, Sax⁴, Sax and Anderson⁵ and by Kato⁶, but the last-named author's work has not been available. An examination of two collections of tropical material, (1) from St Augustine, Trinidad, and (2) from the Botanic Gardens, Port of Spain, has revealed certain interesting features which are reported below. Metaphase associations are given in Table 1, for the two collections separately.

TABLE 1 METAPHASE ASSOCIATIONS IN *Rhoeo discolor*

Coll	Ring of 12	12	10-2	Chams			other	Total
				9-3	8-4	6-4-2		
(1)	6	9	3	3	1	3	15	40
%	15.0	22.5	7.5	7.5	2.5	7.5	37.5	100
(2)	5	10	3	2	3	2	5	30
%	16.7	33.3	10.0	6.7	10.0	6.7	16.7	100

In the first collection, none of the rings of twelve and two only of the chains were disjunctionally arranged, while the corresponding figures for the second collection were one and five respectively. Thus in only 5 per cent of PMC's of the first collection and in 20 per cent of the second were there found disjunctional associations of twelve chromosomes. These figures indicate a considerably higher degree of irregularity than was found by Sax and Anderson⁵ and Darlington², who stated that rings occurred with a frequency of about 30 per cent, angle chains about 45 per cent, and that a "bare majority" were disjunctionally arranged. Sax⁴ gave no details about association but noted that pairing was variable, that chains were more common than rings and that about half of the first divisions examined were disjunctional.

It would be interesting to know whether these differences are genetic or merely environmental in origin, particularly as Sax⁴ found varying degrees of synapsis at lowered temperatures. Such variation emphasizes the dangers attendant on comparison of association frequencies estimated without any control of environmental error (cf Myers and Hill⁷, Benitez⁸ for review of environmental control of pairing, etc.).

An examination of cells between anaphase and telophase, that is, phases of separation in which the chromosomes could still be separately distinguished, yielded the following data (Table 2), in which are given the frequencies of the various types of separation observed, six to each pole, seven to one and six to the other, six to one and five to the other with laggard, etc. In addition, a very few cells were seen with bridges but no fragments; they may be due to inversion crossing-over (Darlington³, Bhaduri¹).

TABLE 2 ANAPHASE-TELOPHASE DISJUNCTION

Coll	6-6	7-5	6-1-5	6-2-4	6-3-3	7-1-4	5-3-4	5-2-5	Total

%	56.1	16.7	18.2	3.0	-	1.5	1.5	3.0	100

It will be seen that, in the two collections, 25.0 to 27.2 per cent of cells respectively contained at least one lagging chromosome (cf the 45 per cent found by Bhaduri¹). There was a well-marked inter-

phase in which complete despiralization took place. In a total of 438 interphases and first telophases in which despiralization had occurred, only 17 (3.9 per cent) were seen in which a chromosome had not been included in one of the polar nuclei, a very marked reduction compared with anaphase. This is no doubt due to the relatively very great volume of the resting nuclei; it must be rare that a lagging chromosome is so placed that it avoids inclusion in the expanding nucleus, once despiralization starts. The few chromosomes that were not so included remained condensed, a situation which has been found in *Tradescantia bracteata* (Darlington³) and *Tripsacum latum* in which an alternative behaviour was the formation of micronuclei (Dodds and Simmonds⁹). It may be surmised that the failure of despiralization is connected with the failure of loss of nucleic acids (cf Darlington¹⁰), and it is suggested that a study of the behaviour of such excluded chromosomes in favourable material might prove helpful in the study of the nucleic acid cycle.

The presence of an interphase is interesting since Sax⁴ stated that "the chromosomes retain their individuality during interkinesis", thereby presumably implying that there was no interphase despiralization. Again, it would be interesting to know whether this is a genetic or environmental difference.

Second division appeared normal, but a few diads were seen in which one cell was at second telophase and the other had not divided at all. In view of the normally high degree of synchronization between cells of a diad, it is possible that such cells represented failure of the second division and might thus have given rise to diploid spores. One second metaphase was seen in which were present two chromosomes apparently joined end-to-end and which had presumably failed to disjoin at the first division. This failure of separation is in accord with the observation of Darlington² but constitutes an exception to his statement¹¹ that undivided associations generally separate during an interphase.

I wish to thank Dr K. S. Dodds for helpful criticism in the preparation of this note.

Plant Nutrients in the Sea

I HAVE recently been attempting a valuation of potential fish production of the banks of the Seychelles-Mauritius arc. The figures following indicate that the suggestion to increase the fertility of suitable parts of the sea by the addition of fertilizers¹ is an established process in certain places and circumstances in the ocean.

The estimated annual basic total catch (catch from professional fishermen only) of the Mauritius fisheries is 1,650 metric tons derived almost entirely from

135 square miles of coastal water, of which 25 square miles is partially reserved by the prohibition of net fishing. The average annual catch is thus rather more than 12 tons per square mile. I believe that the area is fished to the limit of productiveness, so that this figure (area-year production) really has some meaning. The number of professional fishermen is estimated at 1,200–1,500, giving a man-year production (from the more favourable figure) of 1.38 tons. It is interesting to find that a return taken at random from the fisheries census just completed gives the estimated catch of a basket-trap fisherman for the year, excluding Sundays only, as 1.58 tons, which is probably very close to the figure calculated from the totals when the other non-fishing days are taken into consideration.

Figures for Rodriguez, 350 miles to the east of Mauritius, suggest an area-year production of 5.8 tons per square mile and a man-year production of 1.48 tons. The area is not fished to its capacity.

According to Hornell², the Seychelles area of 12,000 square miles, worked by seven hundred fishermen (a "moderate" estimate), produces 1,100 tons, giving a man-year production of 1.57 tons and indicating a very slight exploitation of the enormous fishing area.

In a private communication, written at the end of 1943, G. C. L. Bertram, then chief fisheries officer, Palestine, commented on the "extremely small" catch of the fishermen there—"well under two tons per year on the average".

The similarity of the man-year production figures suggest that the productiveness of the grounds and the other factors—methods of fishing, nature of the fishermen, frequency of bad weather, and so on—are similar in all these places. The intensity of exploitation differs. Five tons per man per year was postulated by Bertram³ for the 'productive' fishery of the south coast of Arabia. This fishery, however, depends on sharks (south-west monsoon, April to September) and then on sardines (October to March), the latter with their large and voracious followers, the tunnies, bonitos and kingfishes. It is a pelagic fishery comparable in its results with the drift-net fisheries of northern waters rather than with the normally laborious process of capturing bottom fishes with hooks and lines.

The islets, reefs and shoals of St Brandon (Cargados Carajos) lie 220 miles north-north-east of Mauritius. The Raphael Fishing Company of Mauritius operates there with about a hundred men who fish with hooks and lines for approximately six months of the year (I give these notes and figures by courtesy of Mr Coucaud, of the Company). From the production of salt fish the man-year production of fresh fish must be at least 8.4 tons. One of the best fishermen brought in, during fifteen days of fishing in August 1944, no less than 798 kgm—a rate of more than 18 tons annually. I say these men work for six months at fishing, for the other six months they are digging guano! The area is about 1,000 square miles of shallows, but only a few favoured localities are fished, so that the area-year production of less than half a ton per square mile indicates slight exploitation only.

The solution, reactions and precise effect of natural guano in the sea have yet to be studied. In the light of certain other facts, a practical application at Mauritius can be projected, and as the argument in its favour bears on the point raised by Dr Atkins⁴ and answered by Prof Ritchie⁵ I make no apology

for summarizing it here. Rapid dissipation into the ocean from the narrow coastal belt around tropical oceanic islands appears likely—as likely indeed as it does from the middle of the North Sea. But many of the economic species of fishes of these islands feed directly on vegetable matter (seaweeds and fixed species of diatoms), so that the conversion of fertilizer into fish is an even more rapid process than that outlined by Prof Ritchie. There is another factor—conservation. Experiments with surface drift bottles off Bermuda in 1932 and 1933 (as yet unpublished) showed a centripetal surface drift during the winter months and a stabilized 'saucer' of warm water oscillating about the islands in the summer, both due to temperature and thermal currents of the shallow waters in and around the islands. In the absence of storms, the coastal water is thus pinned to the land with the pelagic eggs, larval and post-larval stages of the marine organisms, including the fishes, contained therein. Fertilizer spread between tide-marks on such islands as Bermuda and Mauritius would, in my opinion, have little chance of dissipation, but the movements of the inshore waters both here and elsewhere require extensive investigation.

Longevity of *Schizophyllum commune*

In October 1909 the late A. H. R. Buller collected at Winnipeg fresh fruit-bodies of the xerophilic agaric *Schizophyllum commune* Fr. and placed them in his laboratory. On December 10, 1910, a number of whole or part piles were sealed in glass tubes in vacuum of less than 0.1 mm. pressure of mercury and stored in the dark at room temperature^{1,2}. E. F. notes, found recently at Kew with the remaining tubes, show that he planned to test the vitality of the fungus after 1 week, 6 weeks, 4 months, 1, 2, 4, 5, 6, 10, 15 and 25 years. Tradition and experience rate the life of a mushroom as short. Actually, I opened only four tubes: the fungus revived after 1 week, 3½ months, 16½ months, and after 19 months the last three weeks of which were spent at a temperature of liquid air, as noted below.

On March 5, 1945, I opened a tube containing five parts of pilei, moistened them, and placed them in a damp chamber. All expanded, but four of the parts failed to shed spores. The fifth formed a sporangium within a day, and continued to shed spores until it was removed after three days. The spores were normal for the species, 6–7.5 × 2μ, asymmetric and when placed in water some of them germinated. Sections of the gills of this fan-shaped piece of pile 25 mm. long and 15 mm. wide at the edge when moist, showed normal basidia, sterigmata and spores in various stages of development.

Another tube was opened on March 8, 1945, and its contents (one small pileus and a part of a pile removed with sterile forceps, moistened with sterile

ater, and placed on agar. The part-pileus was ad, but the whole one soon formed a spore print id, since there was very little contamination and actically every *Schizophyllum* spore germinated, I adily obtained pure cultures, the hyphae of which veloped clamp-connexions. The living pileus was moved from the agar after two days, placed on a ide in a damp chamber, remoistened and moved ch day. It continued to produce spores sufficient o make a visible spore-print until March 31. Mean- hile rudiments of new pilei developed near the argin, one grew to 10×6 mm, and from its gills ores were shed so as to make a spore print from arch 23 until April 2. This total of 24 days of spore oduction may be a record for the species, at ast it shows that the fungus had maintained its tality.

A few of the remaining fruit-bodies collected during ctober 1909 were taken by Dr Buller to Birming- am where, on June 5, 1912, they were sealed in a ry high vacuum "at about the X-ray stage".¹ I ened one of these tubes on March 1, 1945, it ntained two pieces of pilei, one of which shed ores normally when moistened.

Two or three of the vacuum tubes of 1910 were ken by Dr Buller to Birmingham and immersed liquid air (-190°C) for three weeks in 1912. One as then opened, as noted above. I opened another 1 March 8, 1945, it contained one piece of pileus hich shed spores normally. I obtained pure cultures so from these spores.

Eleven of the vacuum tubes remain for future sts. The four opened each contained a specimen ill living $35\frac{1}{2}$ years after it had developed, $34\frac{1}{2}$ (or, i one instance, $32\frac{3}{4}$) years of which were spent *in cuo*. This is a noteworthy maintenance of 'sus- ended vitality'. Additional evidence is provided in vour of Buller's theory³ that an agaric which sheds ores is alive, and that spores discharged normally e capable of germination.

I do not know whether anyone has tested recently e retention of vitality in *S. commune* kept in 'dry' r. Buller¹ reported that pilei exposed to the u- ally dry air of a room in Winnipeg were still alive ter $6\frac{1}{2}$ years. A pileus collected at Canterbury on ebruary 1, 1935, and filed in Kew Herbarium, re- ved after moistening on March 7, 1945, and shed ormal spores.

Anther and Petal Colour of Potato Varieties

WHILE anther colour has long been used as a agnostic character in the identification of potato arieties, there is a lack of agreement in some of the blished descriptions of the colours. Thus both avidson¹ and Salaman² describe the anther colour e variety Majestic as 'orange' and that of Arjan ctory as 'pale yellow' and 'yellow, pale' respectively, uch indicates some degree of agreement in their e of colour description. Nevertheless, Salaman

refers to the anther colour of Up-to-Date as 'yellow, pale', while Davidson describes it as 'orange'.

To ascertain whether the differences were due to ariation in the anther colour, or to inconsistency in describing it, the colours of the anthers of several arieties from various sources, and, in the majority of cases in two or more years, were matched, after removal of the petals, against the Horticultural Colour Charts issued by the British Colour Council in collaboration with the Royal Horticultural Society in 1939 and 1942. The anther colour of some varieties was found, in fact, to exhibit a certain amount of ariation although the limits of such variation were usually not wide. Its range is given in the accompa- ing table, the number of years over which the exam- inations extended being placed in parentheses after the name of the variety. The name of the colour is in each case followed by its reference number, the number in bold type being that of the full hue of which the colour given may represent a tint, shade or greyed hue.

Petal colours were determined at the same time, and these are also included in the table. Primrose yellow potato flowers are normally described as white.

ANTHER AND PETAL COLOUR OF POTATO VARIETIES		
Variety	Anther colour	Petal colour
Arran Banner (1)	Saffron yellow 7	Primrose yellow 60 1/3
Arran Peak (2)	Saffron yellow 7	Primrose yellow 60 1/3
Arran Pilot (2)	Buttercup yellow 5 to saffron yellow 7	Mineral violet 6 35/1 to Dauphin's violet 0 39/1
Arran Victory (2)	Buttercup yellow 5 to saffron yellow 7/1	Primrose yellow 60 1/3
Ballydoon (2)	Lemon yellow 4 to buttercup yellow 5	Primrose yellow 60 1/3
British Queen (2)	Lemon yellow 4	Primrose yellow 60 1/3
Catrina (2)	Aureolin 3 to lemon yellow 4	Mauvette 5 37 to Dauphin's violet 0 39/2
Di Vernon (2)	Buttercup yellow 5/1	Spectrum violet 7 35/1 to violet 36
Doon Star (1)	Buttercup yellow 5/1	Primrose yellow 60 1/3
Duke of York (1)	Aureolin 3/1	Primrose yellow 60 1/3
Dunbar Standard (2)	Buttercup yellow 5/1 to buttercup yellow 5	Primrose yellow 60 1/3
Eclipse (1)	Empire yellow 60 3	Primrose yellow 60 1/3
Epicure (1)	Buttercup yellow 5	Primrose yellow 60 1/3
Gladstone (2)	Buttercup yellow 5 to chrome yellow 60 5	Primrose yellow 60 1/3 to primrose yellow 60 1/1
Great Scot (1)	Indian yellow 6/1	Primrose yellow 60 1/3
Kerr's Pink (3)	Lemon yellow 4 to buttercup yellow 5/1	Primrose yellow 60 1/3
Majestic (2)	Saffron yellow 7	Primrose yellow 60 1/3
Ninetyfold (1)	Aureolin 3	Primrose yellow 60 1/3
Red Skin (1)	Saffron yellow 7	Primrose yellow 60 1/3
Sharpe's Express (2)	Lemon yellow 4	Rose purple 5 33/1 to pansy violet 00 33/2
Up-to-Date (3)	Buttercup yellow 5/1 to Indian yellow 6	Mauvette 5 37 to Dauphin's violet 0 39/3

The relation between the colours in the table and those in common use is illustrated by the classifica- tion provided with volume 2 of the Horticultural Colour Charts. This shows the gradation of yellow colours from 'greenish yellow' (Dresden yellow 64—the last of the 64 full hues and therefore, on a circular arrangement of colours, adjacent to sulphur yellow 1) through 'yellow' (lemon yellow 4) and 'orange yellow' (saffron yellow 7) to 'yellowish orange' (tangerine orange 9), and of violet colours from 'reddish violet' (orchid purple 31) through 'violet' (violet 36) to 'bluish violet' (methyl violet 39).

VISCOSITY AND LUBRICATION

AT a joint meeting of the Institute of Petroleum and the British Rheologists' Club, held at Manson House, Portland Place, London, W 1, on April 18, five papers dealing with different aspects of flow problems were discussed. Prof E N da C Andrade, president of the British Rheologists' Club, and Prof F H Garner, president of the Institute of Petroleum, were the chairmen for the two sessions of the meeting.

Dr G Barr presented a paper on "The Precision and Accuracy of Viscometry Using BSI Tubes". The paper dealt with data on viscometry collected by the Institute of Petroleum and analysed by Prof Garner and Dr A H Nissan. U-tube viscometers conforming to BSI specifications were sent to a number of laboratories in Europe, the United States and Britain with three oils, with requests to determine flow-times of the oils in the tubes supplied. Further, each laboratory was invited to report the kinematic viscosity of the oils in absolute units at 20° C, according to the method used in the laboratory and country concerned. As a result of analysis of the results returned by some of the laboratories—the outbreak of war prevented many from doing so—it was concluded that dimensional specifications of viscometric tubes were not sufficient to ensure agreement between tubes for the same oil in the same laboratory of better than 0.1 per cent. To ensure such a high degree of agreement a 'dynamic quality control test' is suggested in which flow tests are made on a number of viscometers in order that master tubes may be selected from a set of apparently equally good tubes.

In comparing the viscosity of the oils as measured by British and American methods, it was found that there was a consistent deviation of 0.35 per cent between the two countries. In the discussion it was suggested that the variation in g in different countries might influence the apparent value of the unit of kinematic viscosity in different countries and possibly account for the difference between the American and British determinations. It has since been pointed out by Dr Nissan, however, that the viscometer tubes were calibrated by liquids of known viscosity, and therefore g does not enter into the calculation of these results.

The dynamic control test was criticized in that U-tube viscometers which were found satisfactory by time of flow tests on two reference oils might not be satisfactory for times of flow different from those used for calibration, it would therefore be advisable to use more than two reference oils for calibration of viscometers in the dynamic flow test. The accuracy required in viscosity determinations is to some extent influenced by the determination of viscosity index—a measurement of viscosity variation with temperature—which was discussed in a later paper, the determination of viscosities with a maximum error of 0.1 per cent brings in many factors imperfectly controlled or understood at the present time. Among these factors, in so far as the reference oils are concerned, are thermal and mechanical hysteresis or the solution of air in oil. The influence of errors in timing including that of the operator was discussed. Dr Barr pointed out that in changing from an aqueous solution to a hydrocarbon oil anomalies have been observed which are difficult to explain. If a No 3 BSI tube is used for the determination of a hydrocarbon oil and calibrated at intervals with the 60 per cent sugar solution, difficulties are experienced in

obtaining consistent times of flows, even when the tubes have been very carefully cleaned between the oil and sugar-solution tests. It is difficult to imagine what effect can produce this result, as any retainer film must be much too small to affect the dimensions of the tube.

The second paper dealt with "The Testing of Greases for Ball-Bearings" and was presented by Mr S R Pethrick. It was emphasized that conventional methods for testing greases are of little assistance in the selection of greases for particular applications. It was suggested that tests on lime-base greases should include (1) flow measurements at various rates of shear and at various temperatures; (2) an oxidation test with an examination of the oxidation products, and (3) a syneresis test involving capillary action. Soda- and lithia-base greases vary widely in texture, cohesion and adhesion, and some method of measuring these properties is desirable. The author described an apparatus using the torque exerted on the housing of a ball-bearing rotating under controlled conditions and lubricated by the grease, as a measure of the cohesion, adhesion and lubricating properties of the grease. The stability of the grease can also be determined in the same apparatus by churning it first and then measuring the torque under standard conditions.

The present standard methods of test for greases such as penetration or drop point, while of value for routine checking of a particular product, do not render it possible to select a grease for a particular application without a full-scale test in the equipment to be lubricated.

The development of bearing tests for greases should enable such a selection to be made much more readily and might lead to a more precise definition of physical properties which can be characterized by fundamental measurements.

It was suggested that, in the main, greases are used at moderate temperatures at fairly high speeds and that such conditions should supplement those suggested by Mr Pethrick.

The second half of the session was opened by a paper on "A Rational Basis for the Viscosity Index System. Part I", by Mr E W Hardiman and Dr A H Nissan. The viscosity index of an oil is given as a comparison of the drop in its viscosity between 100° and 210° F with those of two oils, one of low variation in viscosity with temperature (H series) and another of high variation (L series) for the same temperature range. Thus

$$\text{Viscosity Index} = \frac{L - U}{L - H} \times 100,$$

where U is viscosity of the oil at 100° F, cs , L and H are viscosities at 100° F of the series L and H oils respectively, having the same viscosity at 210° F as the oil under test, cs .

Tables were issued by the originators of the V.I. (viscosity index) system from which L and H can be read. This system has been adopted as a standard method for petroleum oils both in the United States and Great Britain. It appears that, for viscosity index values exceeding 140, the value of the index obtained from the tables and this equation are not unique solutions, since two oils both having the same viscosity at 100° F but very different values of viscosity at 210° F can give the same viscosity index. The authors presented a method whereby the index can be calculated as

*Viscosity Index = $(60.0 - \text{antilog } n) \times 3.63$,

where
$$n = \frac{\log U - 0.4336}{\log \text{viscosity at } 210^\circ \text{F}}$$

This viscosity index is a single-valued function. Furthermore, this scale does not differ fundamentally from the Dean and Davis original V.I. system between 100 and 140, but corrects its anomalies above 140. The viscosity index scale was criticized because it is not directly connected with the temperature slope and also because it is not additive as regards mixtures, but it was pointed out that the law of mixtures for viscosity even of pure liquids is as yet not fully understood. From the viscosity index and viscosity at one temperature, it is possible by the use of charts, such as that issued by The American Society for Testing Materials, to ascertain viscosities over a range of temperature, and with a modified scale suggested in the paper this can be done with oils of very flat viscosity-temperature curves such as are now being made by the employment of special additives to lubricating oils. The scale can be applied to oils with no change in viscosity with temperature which would have a viscosity index of around 200 and even to oils which show an increase in viscosity with rise in temperature. The modified scale to be of value in characterizing one of the more recently developed lubricants for which the original viscosity index scale is not satisfactory, it must be adopted as a standard method by such bodies as the American Society for Testing Materials and the Institute of Petroleum Standardization Committee.

Dr. A. Lahiri presented a paper on "The Problem of Engine Deposits", by Dr. E. W. S. Mardles and himself. The paper is an extensive report on rheological and other colloidal studies of oils under oxidizing conditions simulating very closely those existing in internal combustion engines. The oxidizing apparatus can be used as a rotating viscometer of the Stormer type. Studies of specific viscosity have revealed the probable shapes of dispersions in aero-engine oils. The work with the rotating viscometer on oxidized oils has shown that rigidity develops slowly at first with time, then the oxidizing oil suddenly gellates when the concentration and polymerization of the oxidized products reach a critical value. The tendency of oils to keep in suspension soot or other dirt has also been studied. In general, a high degree of flocculation of carbon black, etc., results in high specific viscosity, high sedimentation-rates and times, high rigidities and yield values of the dispersion.

In the discussion it was pointed out that performance tests on lubricating oils for use in internal combustion engines have been extensively developed on engines of different types, but it was felt that these tests are not complete unless information can be derived from the used oils in addition to that obtained from the condition of the engine after the test. The work described in the paper suggested a simple and logical approach to this problem. In the selection of temperatures used for the oxidation tests described, the authors used thermocouples inserted at various points in pistons of aero-engines, and found that the temperature at which the oil functions is of the order of 200–300°C, and hence the fact must be faced that oxidation takes place at such temperatures. Within this range of temperatures there is, however, a marked difference in the behaviour of the oil, thus for the same oil at 200°C gelation

developed in 40 hours, whereas at 235°C 5 hours was sufficient. For the chromatographic examination of used oils columns of 2 in. diameter and 6 ft. long have been used with various adsorption media such as activated silica.

The final paper was presented by Dr. A. S. C. Lawrence on "Lubricating Greases". Lubricating greases are mixtures of soaps dispersed in oil. If a soap is mixed with a hydrocarbon at low temperatures, it exists as a solid suspension. At a certain temperature T_1 , the system assumes a gel structure which it maintains up to another critical temperature T_2 , when it becomes a fluid solution of soap in the hydrocarbon. Peptizers may be used to change suspensions of soap in oil into gels. A tentative structure of the gel by co-ordination was given. The rheology of greases was very briefly given.

Attention was directed to the paucity of information on the temperature-flow relations of greases, although such information would be of direct practical interest and also of great value in determining the energy of flow of the different phases in grease.

The importance of rate of cooling on the structure of greases was emphasized in the discussion, which largely centred about the application of knowledge gained in the investigation of soaps for pure fatty acid to commercial grease manufacture. The character of the mineral oil used is a factor of importance, and certain types of refined oils are unsuitable. Although the water content of greases is very low, and cannot be detected readily by electrical conductivity measurements, it plays an important part in peptization, that is, in increasing the degree of dispersion. It is possible that it acts as a hydrolyser of the soap and that the most effective peptizer is stearic or other fatty acid.

It was pointed out that although greases prepared from more than one metal may result in loss of consistency, in practice lime and soda greases and extreme pressure greases containing lead and calcium are found to be required industrially. Pure anhydrous sodium soaps of the fatty acids have probably never been prepared, although aluminium tri-stearate can be prepared and forms gels as do the other aluminium stearates.

All the papers and discussions reported here will be published in a separate volume by the Institute of Petroleum.

DENTAL HEALTH IN BRITAIN

THE Interim Report of the Interdepartmental Committee on Dentistry (Cmd. 6565, H.M. Stationery Office, 1944) records this Committee's opinion that the dental health of Britain is bad and that its effect upon general health is also bad. The dental profession itself cannot be blamed for this. Its ideals are high. They see in dentistry, not merely attention to teeth, but also that basic relation between dental disease and general ill-health which is the basis of the scheme of dental education outlined by C. Bowdler Henry (*Lancet*, 26, Jan. 6, 1945), who advocates a basic medical education for dental students and also the education of stomatologists who would act as consultants to dentists and would study dental problems in relation to other diseases and to the general biology of man. But the best dental profession in the world cannot operate in a vacuum, it must have the respect and co-operation of the people whom it seeks to serve, and the facts

recorded in this report show that the British people not only do not take full advantage of the public dental services which now exist, but also they do not appreciate the effects of dental disease upon their general health.

As a preface to the discussion of this unsatisfactory position, the Committee outlines the history and present position of the dental profession and its educational and research facilities. Dental education in Britain is given in five dental schools in London, seven in the English provincial cities (Birmingham, Bristol, Leeds, Liverpool, Manchester, Newcastle and Sheffield), three in Scotland (Dundee, Edinburgh and Glasgow), one in Northern Ireland (Belfast) and four in Eire. Before the War, these schools had a capacity of 2,000-2,500, most of them were staffed largely by teachers on a part-time basis, paid or honorary, and some four hundred students a year entered the schools, of whom about 10 per cent were women. Students could prepare for either the B.D.S. degree or for the somewhat lower standard of the licence (L.D.S.), the majority took the licence, the courses for which occupied about five years, while those for the degree were rather longer. Most of the schools have some facilities for research, but most of the staff have little time for this. The dental hospitals provide treatment for the poor and clinical teaching for the students, but neither the hospitals nor the schools have enough money for expansion and improvement. Refresher courses and a limited number of hospital posts provide some post-graduate training. Figures supplied by the Government Actuary indicate that most of the dentists admitted to the register by the 1921 Act are now older than forty-five, so that there will be, in the next few years, a rapid loss of names from the Register by retirement, and the average annual rate of entry to the Dental Register in recent pre-war years in Great Britain was about 340, while the annual rate of entry of students has fallen to below three hundred, some 10 per cent of whom do not, for various reasons, become dentists. It is therefore clear that the Register cannot be maintained even at its present strength. Even if the annual number of persons entering the profession rose to 400 between 1948-52 and to 425 thereafter, it would still be thirty years before the present effective total of the profession would be increased. This is indeed, as this report puts it, an alarming forecast.

Nor is this Committee satisfied with the present position of ancillary dental workers, namely, dental dressers, dental attendants and dental mechanics. The dental mechanic is an essential part of any dental service, and the existing arrangements for the training of dental mechanics are inadequate.

Considering remedies, the Committee concludes that the greatest single step forward would be the creation of a single comprehensive dental service equally available to all who demand it, and paid for by the community as a whole. This service should be an integral part of the Government's national health service, it would give the dental profession its rightful place in the public estimation and would encourage the much-needed recruitment to the profession. In such a scheme certain classes of people, namely, nursing and expectant mothers, children and adolescents, require special attention, and a big expansion of dental services for school-children is one of the essential foundations of a comprehensive health service. All local authorities responsible for schemes of dental health should appoint, as some do

now, a chief dental officer with adequate powers. Quotations from statements made by local authorities show that they are aware of the importance of the responsibilities in this respect.

No dentist, the report insists, should be compelled to enter the public service and all should be able to leave it if and when they desire to do so. Dentists should also be able to engage in whole- or part-time public dental service and in any branch of it. A patient must have free choice of the dentist a liberty to change to another at will. The right of private dental service should especially be preserved. General dental practitioner service should be broad and analogous to that of general medical practitioner service. Dental health centres should be established; they might be experimental at first, the local dentist being consulted about their organization, design and equipment, this participation by dentists in the planning of the dental health centres is emphasized by the report, which would extend it to the planning and administration of the whole dental health scheme.

The report emphasizes the importance of education of the public in dental health. A definite policy of education of the public is required, which should include high quality of dental treatment, education at the health centres, dental hygiene in the school, the encouragement of children to accept treatment, education at maternity and child welfare centres, a supply of publicity material from central sources. The report concludes with the recommendations that suitable ex-Service men and women should be encouraged to become dentists, that dental teachers should be recalled from service as soon as possible, and that dental equipment now being used in the Services should be made available for the public dental service.

The unanimity and brevity of this report enhance its value. Its recommendations should be widely known, for without the intelligent co-operation of the public no health scheme can succeed.

METCHNIKOFF CENTENARY CELEBRATIONS

A MEETING was held at the Opera House in Moscow on May 15 to celebrate the centenary of Metchnikoff's birth, it was opened by G. Miterov, the Soviet Commissar of Public Health. A great gathering of representatives of the medical profession and bacteriology had come together to honour the memory of the great Russian man of science and philosophy.

Ilya Metchnikoff was one of the first Russian Darwinists, and proved by his experimental work the existence of general laws of evolution applying to animal organisms. His biological research on comparative embryology led him to problems of pathology and medicine, in which he obtained epoch-making results, formulating a theory of phagocytosis. After working for a long time at the Pasteur Institute in Paris, he became head of a new school of microbiology investigating especially problems of immunity as it affects medical practice, particularly vaccination. During the latter part of his life, Metchnikoff gave much attention to the study of old age, longevity and death. His point of view was that people do not live so long as they should do, and that, by appropriate modes of living, life could be considerably lengthened.

The role of Metchnikoff in science was the subject of a special paper read by Vassili Parin, general secretary of the Academy of Medical Science. "Metchnikoff," he said, "who obtained such important results in his theoretical work, did not despise practice and gave much time to find a scientific basis for fighting infections and epidemics such as cholera, phoid and tuberculosis. His philosophy was full of optimism and faith in humanity and in the final triumph of science."

Metchnikoff died in 1916, but his numerous pupils in the Soviet Union pursued on a large scale his microbiological research for the welfare of the people. The Opera House meeting was the first of a series of conferences extending over several days, at which reports were presented on various problems of bacteriology, and papers read on Metchnikoff's philosophical conceptions and his work in the fields of arminism, zoology, embryology, immunity, parasitology, microbiology and epidemiology.

To mark the centenary, the Soviet Government has decided to erect a monument to Metchnikoff in Moscow and to put memorial tablets in the University of Kharkov, where he was a student, and in the University of Leningrad, where he lectured. The University of Odessa, where he occupied a professorial air, will bear his name. Metchnikoff gold medals and prizes are to be awarded by the Moscow Academy of Sciences, and Metchnikoff scholarships for students and research workers are to be founded by the Academy of Medicine and by the Medical Institutes of Kharkov, Moscow, Leningrad and Odessa.

A biography of Metchnikoff is to be published, together with a uniform edition of his complete works, and a film on his life and work will be issued in 1946.

LYDIA BACH

SCIENTIFIC AND INDUSTRIAL RESEARCH IN CANADA

A PRELIMINARY review of the work of the National Research Council of the Dominion of Canada in 1944, issued by the Research Plans and Publications Section, in addition to indicating the way in which the Council organizes and co-ordinates its national co-operative research programmes, outlines a few of the major items in the work under the Council's direction.

In aerodynamics, some of the new work involves such problems as balancing of controls on aircraft, work on aircraft skins, the design of tailless aircraft and investigation of factors which arise in their operation. In hydrodynamics there are two main fields—model-testing and basin-tests on aircraft hulls and seaplanes, and hydraulic studies on harbour and river problems, in which such factors as silting, tidal effects, turbulence, location of piers, etc., are involved. Much test work is done on aircraft engines, and unsuspected savings in aviation fuel consumption have been achieved by developing a new type of cracked fuel which can be used in place of straight gasoline in certain operations. Photography has been utilized to study droplets in clouds surrounding aircraft in flight, and physical chemistry has shown the way of dispelling the raindrops which fall on the aircraft's turret and tend to obscure his vision. In the field of applied biology, war requirements have placed great emphasis on the need for work on

foods and their preservation and methods of transport. The development of canning methods for chicken, pork and ham has been undertaken as part of the war effort, and the industrial utilization of agricultural products is an important branch of work. The shortage of rubber led to the study of fermentation methods for the production from wheat of butylene glycol, recently shown to be useful as an anti-freeze, as well as a basis for the production of many useful chemicals. Methods are being developed for modifying wheat starch as a substitute for other starches and for the production of syrups and sugars. A pilot plant using a mechanical method for extracting resin rubber from native plant materials such as milkweed is in full operation.

The activities of the Division of Chemistry have involved much research on adapting substitute materials to war requirements and in developing new methods for strategic chemicals. Substantial advances have been made in the technique of rot-proofing, flame-proofing, and water-repellency treatment of fabrics. The synthesis of new toxic compounds has been carried on as part of the programme of the Directorate of Chemical Warfare and Smoke. Alkaloids from Canadian plants continue to receive attention, and the Paint Laboratory has been occupied with the development of new protective coatings. A new method of glueing based on electrical resistance has been developed and is in commercial use. Research on the prevention of corrosion by the use of inhibitors is continuing, as well as on the protection of aluminium alloys against sea water. Work has also been carried out on the photo-sensitized polymerization and hydrogenation of butadiene.

In the Division of Physics and Electrical Engineering much work has been done during the War on the detection of sound under water at ultra-sonic frequencies. The General Physics Laboratory facilities have been used in such problems as measurement of muzzle vibrations of rifle bullets, ballistics cameras, vibrational measurements, construction and testing of fire-control apparatus, counter chronographs, automatic plotter for air-ground training and other work for the Armed Services. Much work of the Heat Laboratory has been suspended, but infra-red studies and work on land-mine detectors have been carried out with success. The Optics Laboratory has made a substantial contribution to the war effort, and can claim a fair share of credit for the establishment of an optical glass industry in Canada, besides contributing largely to aerial photography. The radio staff has grown to several hundreds, with special laboratories constructed to meet demands for radar studies, and post-war applications may include air-navigation methods, improved blind-landing technique, compact recognition equipment for all types of ships and aircraft and new types of shore beacons to supplement lighthouses, anti-collision alarm signals, etc. Industrial radiology has opened up a wide field of inspection which has been applied in the non-destructive detection of flaws in metal. The X-ray diffraction study of materials is becoming increasingly useful as new techniques are discovered, and electron microscopy is also providing the physicist and chemist with fundamental data not previously attainable.

The National Research Council has devoted much time and thought to preparation for the post-war period, and, under pressure of war, Canada is already spending five times as much on research as in the pre-war years.

FORTHCOMING EVENTS

Tuesday, June 19

ROYAL PHOTOGRAPHIC SOCIETY (SCIENTIFIC AND TECHNICAL GROUP) (at 16 Prince's Gate, London, S W 7), at 6 p.m.—Mr H. K. Bourne "Photographic Light Sources" (lecture-demonstration)

Wednesday, June 20

GEOLOGICAL SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W 1), at 3 p.m.—Scientific Papers

ROYAL ENTOMOLOGICAL SOCIETY (joint meeting with the ROYAL METEOROLOGICAL SOCIETY) (at 41 Queen's Gate, London, S W 7), at 4.30 p.m.—Major H. C. Gunton, M.B.E. "Phenological Relationships of Meteorology and Entomology" Dr C. B. Williams "Fluctuations in Insect Populations as related to Weather Conditions" Dr A. E. Slater "Vertical Air Currents as Agents of Insect Dispersal" Dr B. P. Uvarov "The Organization of Biochemical Research"

Thursday, June 21

LINNEAN SOCIETY (joint meeting with the ZOOLOGICAL SOCIETY) (at the Linnean Society, Burlington House, Piccadilly, London, W 1), at 4.30 p.m.—Major Albert Pam, O.B.E. "The Snake-Venom Serum Institute in San Paulo, Brazil", Mr C. H. Locket "The Availability of Water to Plants in Chalk", Mr W. B. Dowson "The Habits of some Fishes of Nigeria"

Friday, June 22

INSTITUTION OF MECHANICAL ENGINEERS (joint meeting with the MANUFACTURE GROUP) (at Storey's Gate, St James's Park, London, S W 1), at 10.30 a.m. and 2.30 p.m.—A Series of seven Short Papers

PHYSICAL SOCIETY (OPTICAL GROUP) (in the Physics Department, Imperial College, London, S W 7), at 3.30 p.m.—Dr A. F. C. Pollard "Instrument Design"

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned

LECTURER IN PHYSICS at the Burnley Municipal College—The Director of Education, Education Offices Burnley (June 20)

LECTURER IN BIOLOGY, with honours degree in Zoology, at the South-East Essex Technical College, Dagenham—The Clerk to the Governors (June 20)

LECTURER IN CHARGE OF ZOOLOGY (not Botany, as previously stated) at University College, Leicester—The Registrar (June 20)

LECTURERS IN GENERAL ENGINEERING SUBJECTS and in ELECTRICAL SUBJECTS at the South-West Essex Technical College, Walthamstow, London, E 17—The Clerk to the Governors (June 23)

LECTURER IN PHYSICS at the Leicester College of Technology—The Principal (June 23)

A LECTURER IN MECHANICAL AND MARINE ENGINEERING, and a LECTURER IN ELECTRICAL ENGINEERING, at the Marine School of South Shields—The Principal (June 25)

DEPUTY LIBRARIAN at University College, Gower Street, London, W C 1—The Secretary (June 25)

PLANT PATHOLOGIST in the Research Division, Department of Agriculture and Forests, Sudan Government—Ministry of Labour and National Service, Central (T and S) Register, Room 5/17, Sardina Street, London, W C 2 (quoting F 4139 A) (June 26)

ASSISTANT LECTURER IN AGRICULTURE and an ASSISTANT LECTURER IN AGRICULTURAL BOTANY in the University College of Wales, Aberystwyth—The Registrar (June 26)

LECTURER IN FOODSTUFFS in the Manchester Municipal College of Technology—The Registrar (June 30)

A PLANT PHYSIOLOGIST, a PLANT ECOLOGIST, a MICROBIOLOGIST and a FOREST ECONOMIST, in the Department of Forestry, University of Oxford—The Professor of Forestry, Imperial Forestry Institute, Oxford (June 30)

ASSISTANT LECTURER IN THE DEPARTMENT OF METALLURGY, University of Liverpool—The Registrar (July 5)

LECTURER IN ENGINEERING in the Department of Civil and Mechanical Engineering, University of Glasgow—The Secretary (July 9)

TWO UNIVERSITY DEMONSTRATORS IN BIOCHEMISTRY in the University of Cambridge—The Secretary, Appointments Committee of the Faculty Board of Biology "B", University Physiological Laboratory, Downing Street, Cambridge (July 9)

A WOMAN ABSTRACTOR (Ref No F 4217 XA), and two PHYSICAL CHEMISTS with research experience in Rheology or Surface Chemistry (Ref Nos F 4218 XA and F 4219 XA) for a Research Association—Ministry of Labour and National Service, Central (T and S) Register, Room 6/17, Sardina Street, London, W C 2 (quoting appropriate reference number) (July 12)

SPECIAL LECTURER IN BIOCHEMISTRY in the University College of Wales, Aberystwyth—The Registrar (July 15)

LECTURER IN GEOGRAPHY, with special qualifications in Cartography, in the University of Reading—The Registrar (July 16)

STRATHCONA-FORDYCE PROFESSOR OF AGRICULTURE in the University of Aberdeen—The Secretary (August 31)

AN OFFICIAL FELLOW AND TUTOR IN ECONOMICS at Magdalen College, Oxford—The Secretary to the Tutorial Board (Sept 1)

TWO OFFICIAL FELLOWS AT NUFFIELD COLLEGE, Oxford, for research in ECONOMICS AND POLITICS—The Warden (Sept 1)

PROFESSOR OF ELECTRICAL ENGINEERING at King's College, London, W C 2—The Academic Registrar, University of London, Richmond College, Richmond, Surrey (Sept 17)

ABSTRACTORS for articles in foreign languages at the Imperial Bureau of Animal Health, Veterinary Laboratory, New Haw, Weybridge—The Deputy Director

PROFESSOR OF PHYSICS at Canterbury University College, Christchurch, New Zealand—The Secretary, Universities Bureau of the British Empire, c/o University College, Gower Street, London, W C 1
SENIOR ASSISTANT AT THE IMPERIAL BUREAU OF HORTICULTURE AND PLANTATION CROPS, East Malling Research Station, near Maidstone, Kent—The Bureau

LECTURER IN ENGINEERING SUBJECTS at the Medway Technical College, Gillingham—Form of application from Divisional Educational Officer, Fort Pitt House, Rochester

LECTURER IN SOCIAL STUDIES in the University of Edinburgh The Secretary to the University Court

PROFESSOR OF PHILOSOPHY in Natal University College, Pietermaritzburg—The Secretary, Universities Bureau of the British Empire, c/o University College, Gower Street, London, W C 1

CHIEF ANIMAL HUSBANDRY OFFICER, and an ASSISTANT ANIMAL HUSBANDRY OFFICER, for the Berkshire War Agricultural Executive Committee—The Secretary of the Committee, 1 Abbot's Walk, Reading

FIELD STUDIES IN BRITAIN

TO some, in particular to the young reared more or less exclusively in an urban environment, the rising hum of the machine age is as music in the ear—enticing, exciting, novel. Contemplation of mechanical achievement induces a pleasing impression of man's inventiveness, his sense of finding ways and means, his ability to triumph over all kinds of difficulties in the interest of utility.

Our present purpose, however, is not to discuss the merits or demerits of this trend in human affairs, but to indicate that there are other trends which have a special claim on our attention at the present time. In particular, attention may be directed to the advocacy, on many sides and by people of widely diverse background, of the need for encouraging and fostering a love of the countryside and of all the many interests and delights which it can provide for men of quiet mind. To some, perhaps, contact with country life is no more than an occasional need, the response to a passing nostalgic mood. To others it represents an escape from the grime and grind of city life. But these, on the whole, are negative aspects of the call of the countryside. The positive aspect is seen in the actions of those for whom life in the country, involving a close, personal contact with Nature, is regarded as both necessary and desirable because it provides something not to be found in town or city, something that is felt to be essential to the fullness of life.

No short description will cover the attractions which the English countryside can provide. To each one of us, according to his mind, it has something to offer. As our contact becomes more close and intimate, specific interests begin to take shape. These include what might be described as the general interests of the countryman, a combination of the æsthetic, the scientific and the utilitarian, and, more specifically, those of the field naturalist, the geologist, the geographer, the archaeologist and the landscape painter. On each of us the world of Nature, whether represented by the open downs, the moor, the fen, the forest or the shore, lays its spell. Not only do we advance our particular interest and broaden our general sympathies—we also acquire an outlook on life other than that which emerges from the urban daily round. It seems improbable that anyone will seriously dispute the desirability of fostering a knowledge and appreciation of the countryside (and all that this connotes) as part of the educational equipment of a nation that now professes to look forward to a better way of life. Nor will it be denied that it is to young people in particular that this opportunity should be given.

There is nothing new in the pursuit of field studies. No contemporary poem is necessary to extol the joy of the country life or the pleasures of contemplating wild Nature. But two things may perhaps be noted. One is that during the last few decades there has in fact, been a relative decline in field work. The other is that with the development of large towns and suburbs, young people are of necessity being brought up in an environment which daily becomes

more and more completely removed from the realm of meadow and hedgerow. There is, then, a real need for a renewal of interest in field studies. There is also a very real practical problem, namely, how ways and means can be provided to make good this want. On page 744, we publish a paper by Mr. F. H. C. Butler, honorary secretary of the Council for the Promotion of Field Studies, in which the aims, objects, inception and achievement, of this Council are fully set out.

After a perusal of that article, we feel sure that many readers will desire to support the work of the Council by individual subscription and personal advocacy. Such support will be welcome. But the matter should not be allowed to rest at this level. It is not too much to say that the work of the Council, if it can be carried out on an adequate scale, will contribute both directly and indirectly to the national well-being. In that the field studies envisaged have a definite educational, cultural and practical value, they should be regarded as an integral part of the new movement in education. They should therefore be encouraged and promoted by all who realize the value of this work, while, at the administrative level, they should be supported by a grant from the Treasury commensurate with the proposals indicated in the Council's modest but well-considered plan of action. Further, in view of the fact that the Council's work will turn on the acquisition of appropriate centres spread over the country, it can show a good case for the receipt of capital grants. Here the larger philanthropic bodies might well consider whether the Council's objects do not come within their range of interests, and whether they cannot help in establishing the Council on the secure basis which its significance for the future seems to justify.

UNIVERSITY RECONSTRUCTION

The University and the Modern World

An Essay in the Social Philosophy of University Education. By Arnold S. Nash. Pp. 223. (London: S.C.M. Press, Ltd., 1945.) 12s. 6d. net.

THIS essay in the social philosophy of university education is in the nature of a tract for the times, and like most such tracts it is something of *un cri du cœur* and is apt to be stronger in criticism and diagnosis than in constructive suggestions. Mr. Nash faces the fundamental questions of the real function of the university in society which must be answered before we can determine finally its place in the organization and endowment of research or in the educational system as a whole. The problems he raises and discusses are more vital and searching than most of those which Mr. Brian Simon asked and, with the impatience of youth, did not stay to answer. Mr. Nash makes his diagnosis and writes a prescription, though whether the prescription can be made up, or whether its ingredients are available or potent, are matters on which opinion may differ widely.

As to the diagnosis, Mr. Nash is in good company. His main thesis, that the modern university has built up its curriculum and elaborated its educational procedures on the basis of an inadequate philosophy, and that some new unifying principle is needed, is reflected

in much current criticism of the universities. Lowe, for example, in "The Universities in Transformation", in a passage quoted by Mr. Nash, commented that our future intellectual leaders would not be able to understand, and still less to plan, more than a small fraction of social life, unless they knew how to link together the various aspects of their experience into a unity of knowledge. They can only carry out this process if they have learnt how to utilize the findings of the specialist sciences, and at the same time have acquired some direct experience of, say, the particular benefits and strains arising from industrial life, of Nature as reshaped by technique, of social responsibility as increased by planning.

The same thesis is to be found in a recent essay by Prof. John MacMurray on "The Functions of a University" in the *Political Quarterly* and in the 9th edition of Sir Charles Grant Robertson's "The British Universities". It is implicit also in B. Dobrée's essay on arts faculties in modern universities, though not all who recognize as consistently as Rashdall at Mansbridge the unifying influence of a true university would agree that the task of integrating the various branches of learning is specially the function of arts faculties.

Mr. Nash's argument elaborates at greater length this view that a university is not a university at all unless the various faculties and the subjects they treat gain unity of purpose and aim by some common view of man's nature and destiny. It is the substance of his indictment of the liberal democratic university in the first part of his book that the liberal university failed to supply such a view. By rejecting any attempt to discover and then to teach a unified conception of life, the liberal university ceases to be a university, and in the second part of the book Nash argues that students on the continent of Europe embraced Nazism and Communism so readily because the totalitarian philosophies appeared to present only one option to the confusion and chaos of liberal world view which regards each academic subject as autonomous.

In these two parts of his book Mr. Nash writes with unmistakable courage and sincerity. His analysis is impartial, but there will be many who while accepting his view as to the disintegration of the university world and even that the university is facing a profounder crisis than that evoked by the Renaissance or the Reformation, will challenge his conclusions or diagnosis in respect of particular fields. What is at stake, he urges, is a question of the scientific tradition as opposed to the literary tradition as the basis of university education, but the adequacy of the common premise of any tradition now current in the liberal democratic world on the nature and function of the university in human society. Scientific knowledge of man and the universe does not, he holds, by itself provide adequate foundation for intellectual reconstruction, though a place must be found for it in the social structure, and he urges an attempt to discover the limits of reason and the range of validity of scientific method.

Neither that, nor his main thesis, is a new one, but in his discussion of the liberal university, Nash is inclined to attribute a larger place to science as a discipline in the universities than it has actually held. It may well be disputed whether the modern university has ever assumed that the scientific method and spirit are an adequate guide in the pursuit of knowledge. Only last January Sir Lawrence

agg welcomed the admission from the arts side of the six different, though interconnected, realms of intellectual activity of which an educated man would know something included at least the sciences of physics, biology and astronomy. So far from once having been given, at least in the older universities, the place as a discipline to which it is entitled, it may be held that it has been rather omitted on sufferance.

While accordingly it could be maintained that once should have a larger place as a cultural element in education at all levels than it occupies at present, Mr Nash's criticism of the inadequate philosophy of science and of the chaos of liberal atomism whereby the subjects of the university curriculum are separated from each other into neat departments of specialized knowledge is much easier to sustain. In two chapters on the rise and decline of scientific individualism, Mr Nash scarcely allows himself the grace to deal adequately with the issues, and these chapters are suggestive rather than conclusive. Even more challenging is his explanation in the second part of the book of the way in which European trends came to embrace the totalitarian philosophies. His linking of Nazism and Marxism together in this respect will not please all his readers. Both Nazi and Communist, he argues, are right in rejecting the assumption that science has no preconceived bias, in maintaining that knowledge must and does have some purpose greater than itself, and in concluding that all human knowledge is conditioned by irrational factors.

But while Mr Nash agrees with the totalitarian attempt to achieve a synthesis of the different dualisms that give a prominent place to political ideas and concepts by showing the political implications of different realms of specialized knowledge, he sets forthright the totalitarian attempt to unify realms of knowledge by making them subject to final categories and purposes, and by creating a scholasticism which puts the whole of knowledge in a totalitarian strait-jacket. He does not mean that the university must satisfy only the demands which society can make articulate. A university, he holds, discharges its obligations to the social order also by making society aware of what society ought to want. In other words, the breakdown and inadequacy of the three existing philosophies of the relations between the university and social order—what he describes as the spectator theory, the ambulance theory, and the participant theory—lead Mr Nash to advance what may be regarded as the prophet or interpreter theory, and essentially to this that he devotes the third part of his book.

Not even Mr Nash's sincerity renders this partly convincing, but he is himself conscious of its limitations and anxious to inspire a further attempt. In the further volume on "The Reconstruction of the University" which he has in preparation may deal more adequately with some of the questions raised, while Mr Nash is not alone in his plea that the university teacher must accept the responsibility for creation and teaching of a unified and coherent philosophy, and the task of creating a *Weltanschauung* which steers a middle path between liberal atomism and totalitarian dogmatism. Sir Charles Robertson held that theology should be restored to the position of the sciences in the original sense of the 'science', and others like Dr A. D. Lindsay urged that the universities must complete the

education provided in religion as fully and as essentially as in humanism and science if the spirit of the community itself is to be rescued from disintegration.

Mr Nash himself urges that Christian scholars must work out an adequate conception of religious education which, although giving meaning to the whole of knowledge, does not confuse the spirit of the age with the spirit of the ages. His main thesis is developed following a rather inadequate treatment of the sociology of knowledge, the chief value of which he finds in the truth of its thesis that there are fashions of thought which cannot be adequately understood so long as their social origins are obscure. He pleads for a fellowship of lay theologians or Christian scholars who would strive to create a Christian world view within which the conclusions of the specialized subjects of the university curriculum could be given their ultimate meaning in terms of a specifically Christian philosophy of man and of his relation to the historical process.

His plea for an intellectual synthesis for the twentieth century and an interpretation of human life and destiny with a moral or specifically Christian basis is sometimes tantalizing but never without dignity. His treatment of the philosophy of science is short—almost brutal—but Mr Nash is always stimulating. His defence of the freedom of science is sound, and he dispels false ideas in the controversy over science and planning as trenchantly as he does misconceptions of the importance of the university's task of witnessing to the value of the independent and critical pursuit of truth as such and not the buttressing of political or religious doctrines, or as to the entire objectivity or detachment of university thought or teaching.

The relevance of Mr Nash's present book to the problem of university reconstruction is in fact in just this challenge and stimulus to critical and constructive thinking on the philosophy of the university and the content and interrelation of its curricula. Out of such thought must come the creative proposals on which will be based any re-orientation of the functions of the universities to serve the new age. Mr Nash would not claim that he has given us the answers to the questions he raises. He claims that university life and teaching must have a moral and spiritual basis and unity, and is content to start us thinking. His book is a modest but useful contribution to that debate, and its value is increased by an annotated bibliography which, in spite of some surprising omissions—why is Bavinck ignored, for example?—is a useful starting point for wider reading. The production is scarcely in keeping with the quality of the matter and there are too many bibliographical slips for a book of this calibre. R. BRIGHTMAN

COSMOLOGICAL THEORIES

The Idea of Nature

By R. G. Collingwood. Pp. viii+184. (Oxford: Clarendon Press, London: Oxford University Press, 1945.) 15s. net.

COLLINGWOOD'S illness and early death prevented him from saying fully or as effectively as possible all that he had to say. Prof. Knox, the editor, points out that the work now published was written in 1933-34, after the "Essay on Philosophical Method", and was intended as an application of that method. Since the author did not publish anything at the time, we may infer that he was not satisfied

with it. In spite of some later revision it must be taken as no more than a substantial fragment. It suffers more than most of Collingwood's work from a tendency to rash statements and occasional labouring of small points. Nevertheless, the book is a valuable contribution to philosophy, and supplements what we have already of Collingwood's highly original and distinctive way of thought.

The central thesis is that cosmological theories at all periods are based upon analogy. Some familiar aspect of experience is taken as a clue to the character of the whole realm of Nature. Ancient Greek thinkers, almost without exception, conceived of Nature as a living organism. They drew no sharp distinction between the material, the living and the conscious, and they saw the orderliness of the natural world as an expression of its intelligence. After the Renaissance, when machines became familiar, it was conceived as a machine. "The word 'matter' had acquired a new sense: it was no longer the formless stuff out of which everything is made by the imposition upon it of form, it was the quantitatively organized totality of moving things" (p. 112).

Then comes the most challenging part of Collingwood's argument. Since the eighteenth century a new view of Nature has been displacing the older one, a view that does not stress permanence, but rather process, change, development. This means, according to Collingwood, that the natural world is conceived on the analogy of human history, whence these ideas are derived. There follow interesting comments on Hegel, Bergson, Alexander, Whitehead and others, showing how in their hands old conceptions have given place to others, but the process has not gone to completion.

It is here that one sees most clearly that Collingwood's own thought has not reached its own full development. Not only has he cut out the sketch of his own cosmology at the end, but also he has not co-ordinated the stages of the historical process to make clear the way older views have given place to later, as he should have done according to his theory of philosophical method. Moreover, there is only cursory treatment of one of the chief problems—how far at any stage of thought the natural world could be conceived as self-contained and self-subsistent.

Like all Collingwood's work, this book effectively jolts the reader out of common habitual modes of thought. The pity is that it is really no more than a fragment.

A. D. RITCHIE

SCIENCE AND CRAFT OF BEE CULTURE

A Manual of Bee-Keeping

For English-speaking Bee-keepers. By E. B. Wedmore. Second edition, revised. Pp. xxiv+389+9 plates. (London: Edward Arnold and Co., 1945.) 18s. net.

THE honey-bee has been more extensively and deeply studied than any other insect. The craft of bee-keeping has perhaps the most complex technique that has ever been developed for the domestication, or perhaps it is safer to say the exploitation, of any livestock. This is due to the highly developed social life of the bee, with its infinite variety of possible reactions to stimuli not always understood or controllable by man. It is not surprising, therefore, that

there is a very extensive literature dealing with science, art and craft of bee culture.

The author of "A Manual of Bee-Keeping" deals entirely with bee-life, its science, and the technique of bee-keeping, and does not interpolate extra from the classics or the poets. He deals in fact. After a life-time spent in research work, he has keen sense of scientific caution, and adroitly avoids giving unproved theories or indulging in flights of fancy. All the time he presents facts in clear, critical form. It is to be hoped that readers will appreciate that when the author of this book gives instructions for an operation involving a sequence of steps at intervals indicated in precise words, deviation from literal accuracy in taking those steps is allowed for, otherwise trouble will be encountered.

The general arrangement is encyclopaedic, and paragraphs are numbered—some 1,600 of them—with cross-references to all related subjects. There is nothing to tie the book to bee-keepers in one country and render it unsafe to use in another. It gives facts about honey-plants and current practice in both hemispheres, and general management of bees much the same all over the world, so that it may be described as of international application.

It is significant that among the traditional notions that the author discredits is the persistent belief that each baby bee that emerges from its cell leaves behind its cocoon skin adhering to the walls and base, so that the size of the cradle diminishes with each successive generation that uses it until only undersized bees can be reared. Much searching has had to be done to reveal any comb with cell walls more than thousandths of an inch in thickness, whatever their size.

Pollen, which was for so long regarded as a nuisance in the combs that writers used to give elaborate instructions for getting rid of it, receives full recognition of its value in no uncertain terms. So readers will be surprised to learn that well over a hundredweight of pollen is used annually in a normal bee colony, and that in summer the daily gathering of pollen may exceed two pounds. Annual consumption of honey will be about four hundredweight with some few gallons of water, so that the total food consumed by the bees is considerably in excess of a quarter of a ton per hive.

Bees have normally been cleared from filled spaces by boxes of honey by use of a device called a Porter escape, which causes the bees to walk between delicate springs through which there is no return long as nothing happens to jam the springs. The author illustrates a device of his own designing which has no movable parts to become fixed. It operates on principles similar to those employed in some crab traps.

The important discovery that bees will tolerate a space of about $\frac{1}{4}$ in. between frames of comb and sides and floor of the hive without filling it with wax was published in 1852 by L. L. Langstroth. It appears, however, from evidence adduced by Wedmore, that Debeauvoys published in 1851, in "Guide de L'Apiculture" a description of a space of 6 mm. which could be used in the same way, so he would appear to have anticipated Langstroth's announcement. There was, however, the difference that in France the discovery passed unnoticed, so that in the English-speaking world the American's made a great stir.

Altogether, Wedmore's "Manual" is a book for the serious student, for the practical man, and as a present to both classes.

H. J. WADSWORTH

Diseases of Vegetables

Bulletin No 123 of the Ministry of Agriculture and Fisheries By Lawrence Ogilvie Second edition 11+74+8 plates (London H M Stationery Office, 1944) 1s 6d net

THIS is the second edition of the now well-known bulletin on diseases of vegetables written by L. Ogilvie, advisory mycologist for the Ministry of Agriculture's western province, with headquarters at Long Ashton Research Station, Bristol.

Among the expert mycologists comprising the Ministry's team of advisers, no one is more fitted than Ogilvie to write this bulletin. His province includes five counties within the boundaries of which are to be found some of the best vegetable-growing areas, cultivated by some of the most progressive growers of market garden produce. Long years of experience coupled with his considerable number of investigations into many diseases of vegetables have won Mr Ogilvie such knowledge of the problems which arise in the successful cultivation of vegetables to render his advice extremely valuable to growers of these crops.

After a brief but lucid introduction explaining the nature of the various kinds of disease, the ones attacking vegetables are described and appropriate measures for preventing or checking them are given. The diseases are referred to by the accepted common name (standardization of which for Great Britain has been attempted in the List of Common British Plant Diseases recently published by the Cambridge University Press), but the full scientific name of the organism causing the disease also appears in brackets after the common name.

Compared with the first edition, there has been some revision and addition in the light of recent discoveries by research workers. There are a score or so of excellent photographs to illustrate some of the important diseases.

Following the main part of the bulletin dealing with vegetable crop diseases, there is a small but useful section giving descriptions of such practices as soil sterilization by steam and chemicals, seed treatment, preparation and use of fungicidal sprays and dusts, disinfecting of glasshouses, etc. There follows a list of the Ministry of Agriculture advisory mycologists with the counties administered by each; this is of great use in indicating where growers can apply for advice on crop troubles.

It is an extremely well set up publication which every grower of vegetable crops ought to have. The information it contains is written by an expert, and at a price, as usual with these bulletins, is within reach of everyone's pocket. D E G

Radio Technique

A G Mills Pp viii+170 (London Chapman and Hall, Ltd, 1944) 12s 6d net

Radio Receivers and Transmitters

S W Amos and F W Kellaway Pp x+281 (London Chapman and Hall, Ltd, 1944) 21s net

THE paucity of new text-books concerned with radio transmission makes the above pair particularly welcome. While we cannot subscribe to the claims of the first author that his text covers among other matters a thorough treatment of transmission and reception necessary for the complete understanding of radio, nevertheless what he has attempted

the young student in a restricted field is well done, and gives a very good idea of the theoretical

background necessary in every telecommunications engineer whether specializing in radio transmission or not.

The authors of the second book are slightly more ambitious, they link up the theoretical work with practice and bring in topics too numerous to mention here. There are many applications of valves which must wait for general disclosure, but this book will certainly impress the student that there are important applications of radio technique, and that to understand them—and in the future to introduce new ones—it is necessary for him to learn much relevant fundamental work. The authors, while not exhausting the subject, have made a careful selection which can be recommended with confidence. L E C HUGHES

Organic Reagents for Organic Analysis

By the Staff of the Research Laboratory of Hopkin and Williams, Ltd Pp 172 (London Hopkin and Williams, Ltd, 1944) 5s 6d

ESSENTIALLY a summary of a good deal of information hitherto available only in a dispersed form in recent chemical literature, this book provides a comprehensive list of organic reagents which may be used in identification work for the preparation of crystalline derivatives of various organic types. To illustrate its scope, we may note that under the alcohol type are given eight 'selected reagents' and eleven 'other reagents', the former being as a rule more satisfactory and easier of access than the latter, for details of which the reader is referred to the original literature. Choosing 3,5-dinitrobenzoyl chloride as a typical 'selected reagent', we find a description including its structural formula, molecular weight and significant properties, with experimental details for its use in preparing derivatives of alcohols and phenols, together with notes on other applications, a bibliography, and references to tables of melting-points given at the end of the volume. To name a less familiar example, xanthidrol is described, on a similar plan, as a reagent for amides, urethanes, sulphonamides and substituted barbituric acids. There is a good index.

The book is evidently an outcome of much first-hand experience, and will be a valuable adjunct to teachers, students, research workers and others concerned with qualitative organic analysis. J R

Bentley and Driver's Textbook of Pharmaceutical Chemistry

Revised by Dr John Edmund Driver Fourth edition Pp ix+644 (London, New York and Toronto Oxford University Press, 1945) 21s net

THIS book is widely used by those who have passed preliminary scientific examinations and are studying for the qualifying examinations in pharmaceutical chemistry. Its suitability for this useful purpose is attested by the appearance of four editions in twenty years. It is divided into three sections dealing with analytical methods, inorganic chemistry and organic chemistry respectively, and is full of facts clearly and simply set forth. A large proportion of these facts is taken from the "Pharmacopoeia", with suitable explanations and amplifications. A few references are given to original papers, but the book is essentially an elementary textbook for a specialized purpose. The new edition has been brought up to date by the inclusion of data from the first six addenda to the "British Pharmacopoeia" of 1932 and revised throughout in the interests of accuracy and clarity.

THE COUNCIL FOR THE PROMOTION OF FIELD STUDIES

By F. H. C. BUTLER

Honorary Secretary

IN all branches of knowledge which deal with the nature or configuration of the earth, or with its animal or plant population, or with human ecology, past and present, teaching cannot be adequate unless the student can learn in the field as well as in the lecture-room, library and laboratory, this is equally important whether he is to become a teacher, an administrator or a research worker. It is difficult, often impossible, to carry out adequate field excursions from school or university. The time taken in travelling to and from any but the nearest localities leaves little opportunity for serious work, the carriage of apparatus and equipment is also a major problem. Moreover, in research it is often necessary that continuous observations in the field should be carried out over long periods, this is essential where the subject-matter of a problem is so great that its adequate investigation will take many years, for example, the detailed geological or geographical study of selected areas, or the study of fauna and flora. It is equally essential where seasonal changes are all-important, such as the effect of weather on coastal configuration, or the observation of seasonal changes in the fauna and flora of the sea, lakes and rivers, or on the land. A great deal of the biological field-work done at present loses much of its value because of the impossibility of making regular observations in the same area throughout the year.

In order to meet such difficulties on an adequate scale, the Council for the Promotion of Field Studies was founded in 1943, a report of the inaugural meeting was given in *Nature* of December 18 of that year. A leaflet was issued by the Council last June giving a brief description of its aims, membership, proposed constitution and current activities. In February this year the first number of the *C.P.F.S. Bulletin* was published. The aims of the Council are to provide facilities for every aspect of field-work at first-hand, and to set up for this purpose residential field study and research centres, distributed throughout Britain, in localities selected for the richness and variety of their ecological features, geological and geographical interest and archaeological and historical importance. The field centres will be available alike to all serious workers in the field, whether amateur or professional, whether as individuals or as members of a class from a school, training college, university, young people's college, youth club, or other corporate body. The Council wishes to co-operate closely with local societies and field clubs, and through the centres—many of which will be situated in or near Nature reserves or national parks—should be able to play an important part in the training of the community in sound knowledge, æsthetic appreciation and proper use of the countryside.

The Council is working in close co-operation with the National Trust, which is fully in sympathy with its proposals. It is hoped to establish the field centres so far as possible by leasing National Trust properties, care being taken in their adaptation and use to ensure their preservation as national monuments, while at the same time putting them to a cultural purpose. For the establishment of the first field centre, the

National Trust in 1943 made an offer to the Council of the lease of Flatford Mill and Willy Lott's Cottage in East Suffolk, made famous by Constable, an admirably suited to scientific and artistic studies. Prof. W. A. F. Balfour-Browne made a generous grant to cover the first year's rent, and application was made in June 1944 to the Carnegie United Kingdom Trust for a capital grant towards the considerable cost of adaptation and equipment. The Trustees expressed their interest in the aims of the Council and agreed to contribute up to £2,000 for this purpose. Negotiations with the National Trust for the lease of this property have therefore been concluded, and when labour and materials become available the work is to be carried out under the professional direction of Mr. Marshall Sisson, who has been appointed consulting architect to the Council. The family of the late Miss Alice Hibberd Ware has generously presented her unique collection of natural history material for the use of students at Flatford. It is hoped to dedicate the library to the memory of James Reid Moir, the well-known Ipswich field archaeologist, who did so much of his scientific work in the neighbourhood and who lived in the Mill House for the last five years of his life; he greeted the foundation of the Council for the Promotion of Field Studies with enthusiasm and his help would have been invaluable.

It is the unanimous view of the Executive and General Committees of the Council that the success of its scheme depends on the possibility of establishing a number of field centres in different parts of Great Britain more or less simultaneously as soon as possible after the general conclusion of world hostilities, to be followed by others as occasion and opportunity offer. The general demand for property suitable for centres is rapidly increasing, for the Council's needs their precise location is of paramount importance on ecological grounds, it is therefore essential that the Council should be in a financial position to take urgent selective action before it is too late, as present opportunities are never likely to recur. Regional sub-committees covering England and Wales have been appointed to advise the Executive Committee on the selection of suitable sites, with the requisite accommodation for centres in their areas. Mr. Hubert Smith, chief agent of the National Trust and a member of the Council executive committee, is kindly advising the sub-committees when suitable Trust properties become available.

In addition to the grant from the Carnegie Trust the University of Cambridge, on the recommendation of three faculty boards (Biology 'A', Geography and Geology, Archaeology and Anthropology) and the General Board of Studies, has agreed to put the capital sum of £600 at the disposal of the Council towards initial expenses incurred in establishing field centres. The University of Bristol and the University of Leeds have allocated token annual grants and donation has been received from University College Hull. Owing to the unique opportunities for teaching study and research in the field that will be made available to them as the centres become established the Council looks to each of the other universities for at least token financial support at the earliest possible moment. As the Council's work will involve the management and ownership of property, with gradually increasing financial responsibilities the Executive Committee considers it essential that the Council should become incorporated under the Companies

times Act, 1929, and the necessary application is being made. Under the constitution, the General Committee of the Council will be the statutory body responsible for the formulation of policy, the direction of activities and the election of the executive. It is composed of representatives appointed by the universities, scientific societies and institutions, leading organizations of the teaching profession and the main groups of natural history societies, field and club. The Council's work will embrace very wide and varied interests, and, in order to be fully representative, the General Committee must necessarily be a large and influential body; it is clear that equality in the election of official representatives cannot be reached until the Council gets into its stride, and it is important that this should be borne in mind. It is proposed that one quarter of the General Committee should be representatives of individual members.

At the first meeting of the General Committee held in the Royal Society's meeting room on April 25 the following resolutions were passed unanimously:

(1) This representative meeting strongly urges the great potential value of the work of the Council in the scientific, educational and cultural importance of taking immediate measures to establish a number of field centres actively in operation in different parts of the country.

(2) That the Executive Committee be instructed to take immediate measures to put this view before appropriate Government Departments, the Carnegie Trust and other bodies, with a view to securing a direct grant from the Treasury, and any other assistance which offers means of realizing the early fulfilment of our programme.

In some respects, the Council for the Promotion of Field Studies will perform for the culture of the countryside what the Council for the Encouragement of Music and the Arts has been doing for the presentation of music and the arts to the community. Not only will it introduce the serious first-hand study of the countryside to a new and to a much wider public, but so "the Council will," in the words of Prof F. T. Lewis of Cambridge, "fill a very important gap in our system of education, both at the school and university level." Its functions are concerned with processes and not merely with the products of intellectual achievement. It will play a vital part in many branches of research. Its financial needs are therefore no less great than those of C.E.M.A., and worthy of at least equal consideration for a direct Treasury grant.

The field centres will be staffed and equipped to provide adequate board, lodging and working facilities for numbers ranging up to forty or fifty students. They must cater for a wide variety of needs and interests—for every science and art the natural province of which is (or ought to be) the open air. They must be able to provide ample and varied material for study, attractive and comfortable but not extravagant living accommodation, the right tools and books and elbow-room during working hours, congenial and useful occupation in spare time. In function, they may be fairly described as residential university outposts in the field, for they would be field extensions of the departments of botany, zoology, geography, geology and archaeology, all of essential use to students of history, dialect, place-names, folk-lore, anthropology, antiquities, art, agriculture, forestry, architecture, town and country

planning, rural crafts, economics, sociology, and so forth. As it gradually becomes fully equipped, a field centre must combine adequate facilities for field work with some at least of the social amenities of a residential college. A field centre would, in short, offer its students something far more tangible, more lasting, than the limited experience of the 'day-excursion' or of the 'bench-experiment' kind.

Each centre will be under the direction of a trained warden. Although it is intended that classes of school and university pupils shall be accompanied by their own teachers, it is essential that the wardens of the field centres should be experienced naturalists and trained field-workers with wide cultural sympathies; they must be able to undertake specific instruction in the field in their own subject as well as advise on other activities in which an intimate general knowledge of the district will be necessary. The position of warden will be one of peculiar responsibility—he will have to direct, advise and collaborate in every way possible—and obviously on him will depend to a very large extent the success and efficiency of a centre. It is considered, therefore, that the post should carry with it a status comparable to that of a university reader or professor.

As well as the student and professional research worker, the Council is especially anxious to attract and help the amateur—the 'born' naturalist, artist or archaeologist—and hopes that local societies and field clubs will co-operate closely with the work of the centres. At each centre there must be, for the novice, expert help and individual encouragement, for the advanced student, every facility for research—the standard must be high in personnel and equipment. For professional research workers from institutions like Wray Castle and Rothamsted, there must be facilities for obtaining comparative data in fundamental long-term investigations, each centre should be an ecological research station and have places reserved for investigators who wish to stay for long periods.

We have mentioned that the centres could be regarded as field outposts of various departments of a university. An important point is the co-operation which could be instituted at a centre between the work of different departments even of the same university. At present these function independently, but all would gain greatly if combined work were done. For example, biologists and archaeologists would have the advantage of information about the geological formation of the area, for the maps and surveys of the geographers would be of service to them, while both geologists and geographers would benefit from first-hand information concerning the fauna and flora. Geologists could receive instruction from geographers in the methods of trigonometrical survey and tachymetry. Also, meteorological data and climatic (or micro-climatic) investigations would be fundamental to many studies. Thus students in different subjects would have the great advantage of working together, seeing each other's methods and results and learning, at first-hand, of the unity of knowledge, which is an ideal so difficult to attain within the somewhat water-tight compartments of a university. There would be further and wider advantages both of a social and cultural nature. Members of the staff as well as students of one university would meet those of other universities in their own as well as in other subjects, when staying at the same centre together. Furthermore, the association of art and science, under the informal and fortuitous circumstances in which their practi-

tioners would meet, would at least be interesting and might well be beneficial to both.

For secondary schools, the centres would afford admirable opportunities for individual or group work in many subjects, including natural history, biology, geology, geography, history, art and allied studies. Many school syllabuses in biology—largely dictated by external examinations—are too academic to appeal to the average boy and girl, and are, therefore, not of the real educational value that they should be. Children are interested in studying living plants and animals in their natural environment, and it is coming to be realized among educationists that this aspect of the subject needs to be greatly encouraged, but unfortunately, few teachers—including university graduates in the biological sciences—have the requisite first-hand knowledge and experience of field-work to teach natural history with competence and enthusiasm. In biology (a subject which purports to be the science of living things), it is far easier to teach and examine classes of pupils by anatomizing dead specimens in the laboratory than by observing living organisms in the field, and this may account for the comparative neglect of the study of animals and plants in their natural habitats.

The evacuation scheme, whereby the schools were dispersed from the cities of Britain into the countryside during the War, has shown only too clearly that for many teachers the countryside is a closed book, comparatively few seem to have been able to make use of the excellent opportunities presented to them for first-hand observation and teaching in the field, even when there was no external examination syllabus to tie them down to an unadventurous and monotonous urban class-room routine. Moreover, in schools permanently situated in the country, it is the exception rather than the rule to do any serious work in the field in school hours, in studies (other than gardening) which specially lend themselves to observational work and the testing and illustrating of teaching and text-book authority at first hand. Admittedly, this work requires detailed knowledge and a carefully planned technique, which are at present outside the range of experience of many teachers in the schools, not having been demanded in their university studies or dealt with in their courses of professional training. The centres will be equipped and organized to enable this special knowledge of field-work to be acquired by teachers and pupils in the various subjects, also teachers will be able to learn the technique of handling classes in the field, which undoubtedly requires special training, experience and facilities, if the work is to be efficient and time and energy conserved. In course of time, perhaps, when the centres have become widely established, new influences will be brought to bear on school and university teaching and examining, and then the Council for the Promotion of Field Studies will be "filling the very important gap which exists in our system of education both at the school and university level." It is hoped that the centres will be widely used by teachers and pupils in the schools, and that they will enjoy working out the fresh approach to culture that field-studies will bring them, with new kinds of technique, in places of great natural beauty that should rejoice the hearts of artists and craftsmen, as well as scientific men, geographers and historians.

Finally, the Council for the Promotion of Field Studies is a scientific society, and therefore it is important that the spirit of research should not

be confined to field and laboratory, but should be applied to the planning, organization and equipment of the centres, and indeed, to the general administration of the Council's activities as a whole. While these activities will be in their completeness it is not yet possible to forecast, but from the widespread and eminent support that the Council has already received, it would seem that we are on the fringe of great possibilities of service to those who wish to make a first-hand study of the many branches of knowledge that have their source and inspiration in the field.

THE SEVERN BARRAGE SCHEME

COAL supplies in Great Britain having become deficient in quantity and quality, public attention has been forcibly directed towards alternative sources of power and energy. The most novel and also the largest single source which has attracted public interest is the Severn Barrage. A scheme formulated by Mr A. G. Vaughan-Lee, Sir William Halcrow and Mr S. B. Donkin, published by the Ministry of Fuel and Power*, gives a broad outline of a method of utilizing tidal power in the Severn Estuary, provides an estimate of the amount of power and energy which would be made available, and the cost thereof.

The principle of the scheme is simple. A dam across the Severn enables water to be impounded during rising tides. This water flows through turbines during the succeeding falling tides. Its potential energy is converted to kinetic energy by the turbines and then to electrical energy by alternators directly coupled to these turbines.

The proposed dam is located at the English Stone some two and a half miles downstream from the mouth of the River Wye, a rough locating point on the north bank of the Severn being the village of Snabrook. It is about two miles long, and comprises sections for inlet sluices, navigation locks and turbines. Thirty-two turbines, in two equal groups, would drive thirty-two alternators, each rated at 25 MW at 0.9 power factor. These would be capable of providing a maximum power output of 800 MW. At spring tide, when the power available is greatest, the total output from the alternators would rise to a maximum of 800 MW in two and a half hours, remain at this value for four hours, and then fall to zero in a further period of about one hour. There would thus be two periods of about seven hours during each twenty-four, in which the plant would be able to generate power and energy. The maximum power and the hour at which it is available changes day by day in accordance with the state of the tide. The daily and seasonal changes of the power and energy output are to be balanced by suitable operation of the barrage power in conjunction with the electric grid system of Britain.

The gross energy available at the barrage would be 2,365 million kWh per annum. If the water flow through the turbines were continuous, the energy available per annum would be 7,008 million kWh.

The ratio $\frac{2,365}{7,008}$, that is, 0.47, is important with

* Ministry of Fuel and Power. Report of the Severn Barrage Scheme by A. G. Vaughan-Lee, Sir William Halcrow and S. B. Donkin. 32 (London: H.M. Stationery Office, 1945.) 2s. 6d. net.

considering the relative merits of the barrage scheme and of other sources of energy, such as interconnected thermal power stations, where the maximum output can be maintained continuously if some 15 per cent of spare plant is provided. About one million tons of coal per annum would be saved by using the Severn power. To maintain constant electrical frequency and output, the turbines are to be of the Kaplan type, with variable-pitch propeller-type runners. The magnitude of the project can be gauged by considering the quantity of material to be used and the labour to be expended.

Civil engineering materials, cement, stone, sand and gravel	6,585,000 tons
Steel	89,000 "
Copper	5,000 "

The labour required for manufacturing plant and constructing the barrage would be 86,840 man-years. The report suggests that the constructional time could be eight years, with an average of 10,355 persons in service over that period. The estimated cost of the barrage (1944 basis) is £40.22 million. This is £50 per kW of plant installed. Thermal power stations cost about £30 per kW, but they have a power-delivering ability of about 85 per cent compared with 47 per cent for tidal stations. They can also be sited closer to power-consuming centres, and can be operated to suit the load requirements.

Ordinary hydro-electric stations, such as are scheduled for construction by the North of Scotland Hydro-electric Board, will cost about £53 per kW. Their power availability factor is not precisely known, it should be of the order of 80 per cent, and is certainly far higher than that of a tidal scheme.

Viewed from the conventional economic point of view, the prospects of the Severn Barrage scheme appear to be bleak. It is, nevertheless, possible or even probable that it will become expedient to construct the Severn scheme in the fairly near future. This renders it particularly interesting to consider its aspects from a practical engineering aspect.

No justifiable doubt exists as to the ability of British engineers to construct the barrage, civil engineering works and electrical equipment. Laymen are liable to be apprehensive about possibilities of disaster, or at least crushing expenditure due to erosion downstream, and silting upstream from the barrage. This aspect has, however, been fully justified by an admirable series of experiments made.

Prof. A. H. Gibson on a scale model of the relevant part of the Severn estuary with and without the barrage. A detailed survey of the estuary made by the Admiralty in 1849 had established the contours of the river bed at that time. Prof. Gibson was able to show that he could reproduce on his model the changes which were caused in the undammed Severn by scouring and silting. Similar experiments on the model provided with a barrage enabled Prof. Gibson to indicate, it is believed accurately, what will take place in the Severn over a period of sixty years after the Severn scheme is put into service.

Prof. Gibson's remarkable investigation, in the best tradition of Osborne Reynolds, has made it possible to predict accurately what the total costs of electricity generated at the Severn Barrage will be over a long period of years. The figure for the energy cost given in the report is 0.199d per kWh at the barrage.

There is an unfortunate tendency on the part of the public to hamper development of schemes of the Severn Barrage class because they are deemed

to be 'huge', nevertheless the fact remains that its cost is only the equivalent of some three days of the British expenditure during the War.

In this connexion, it may be useful to direct attention to a water-power scheme at Catrine, Ayrshire, which was put into service in 1837, and which continues to function to this day, as perfectly as it did initially. The Catrine scheme uses the power of the River Ayr. Two overshot water wheels, each 50 ft in diameter, develop 800 h.p. This power is transmitted to a factory by a shaft 200 ft long. The hydro-power fluctuations are evened out by a 200 h.p. beam, which started work in 1847 and which is still in action.

Although the Severn Barrage is about a thousand times as large as the Catrine scheme, considered as a risk to the community it is trifling compared with that faced and overcome more than a hundred years ago by forgotten Ayrshiremen. Those now responsible for electrical development in Great Britain are not lacking in enterprise, and will doubtless set the Severn to work at its appointed time.

SYMBIOTIC NITROGEN FIXATION

By PROF. ARTTURI I. VIRTANEN

Biochemical Institute, Helsinki

SINCE 1940 I have not had the opportunity of reporting to English readers the results of our investigations on symbiotic nitrogen fixation. As an opportunity now offers itself, I will briefly record in the following the chief points of our research during the War.

Oxaloacetic acid, which according to my conception has a central position in the formation of aspartic acid, has been determined in several leguminous plants at different stages of growth and under different lighting conditions, employing a method previously described¹. The oxaloacetic acid content of the plant is highest at noon and in the afternoon, lowest after the night. If the plants are kept for two days in the dark, the oxaloacetic acid disappears. The pea contains before flowering usually about 50 γ oxaloacetic acid per 1 gm, determined at noon, and red clover about 100 γ. At the end of flowering and when growth ceases oxaloacetic acid is no longer detected in plants².

We have been able to isolate bacterial strains of *Rh. leguminosarum* which causes nodulation on peas but do not fix nitrogen at all (in ten experiments, inoculated pea plants contained on the average 7.5 mgm N per plant, uninoculated control plants 7.3 mgm). By using our sterile culture system, we have been able to show that this is a constant property of this bacterial strain. Although the bacteria were allowed to pass through five plant passages they did not become active nitrogen fixers. The experiments with ineffective and very effective bacterial strains have without exception led to the conclusion that all the reports in the literature on the change of an ineffective strain to an effective one and *vice versa* through successive plant passages are erroneous and due to the fact that the experiments have been carried out in open pots. In such conditions there is always a great danger of contamination by foreign strains. Only in a sterile culture system can reliable results be obtained.

In comparing the root nodules of the pea formed by an entirely ineffective strain (H VIII) with those formed by effective strains, the following differences can be noted

(1) In a sufficient concentration of oxygen, the root nodules formed by effective bacterial strains always contain a red pigment, the interior of the nodule being bright red in colour. The red nodules are active nitrogen fixers.

(2) The nodules formed by the ineffective strain H VIII never contain red pigment and do not fix nitrogen.

(3) In oxygen-free conditions even the nodules of effective strains have no red pigment. These nodules do not fix nitrogen.

(4) If the plants are removed for two or three days into the dark the red pigment turns green. The green nodules are no longer able to fix nitrogen, even when the plants are again brought into light.

All the observations show undoubtedly that the red pigment is essentially associated with the nitrogen fixation and is necessary to this phenomenon. Similar evidence has not previously been furnished of the significance of the red pigment in the leguminous root nodules.

The red pigment of the effective root nodules is not a derivative of dioxyphenylalanine, as assumed by Mothes and Pietz³, but a haemoprotein as Kubo⁴ has shown with the red pigment he isolated from the nodules of soya bean. We have noted with the haemoprotein extracted from the effective root nodules of pea the absorption band at 556 m μ . If the solution is vigorously shaken, the oxyhaemoprotein is formed with absorption bands at 575 and 540 m μ . Also the absorption bands of other haemoprotein compounds correspond approximately to the bands given by Kubo. Thus we have been able to confirm his results. Accordingly, the haemoprotein is a haemoglobin which functions as a store and as a carrier of oxygen. Whether this pigment has also other functions specifically connected with the nitrogen fixation is unknown. The combination of haemin-iron with nitrogen or nitrogen compounds is also a possibility.

[Prof. Virtanen was, of course, unaware of the article "Haemoglobin in the Root Nodules of Leguminous Plants" by Prof. D. Keilin and Dr. Y. L. Wang, published in *Nature* of February 24, 1945, p. 227. Editors.]

The change in the colour of pigment from red to green—demonstrated also in the sterile culture system after the plants have ceased to grow—shows that the red pigment undergoes a change as the activity of the nodules comes to an end. It can be assumed that the ring system is thereby broken and possibly products of pseudo-haemoglobin-type of H. Fischer are formed. The properties of the green pigment are being examined more closely. Likewise we are just doing some experiments to find out whether the nitrogen fixation can be accomplished in cultures of free-living legume bacteria to which has been added haemoglobin of root nodules and oxaloacetic acid. As the bacteria apart from the host plant are not able to synthesize haemoglobin, one reason for the inability of the free-living legume bacteria to fix atmospheric nitrogen must lie in the lack of haemoglobin.

In examining the effectiveness of different strains of nodule bacteria, we have given attention also to the immunity which is brought about by the bacteria

first invading the nodule. For this purpose we have also used the sterile culture system. The results have been as follows.

(1) If the seed of the pea is at first infected with the ineffective strain H VIII and, after the appearance of the first nodules, the culture medium is inoculated with an effective strain, this is no longer able to form nodules. The pea ceases therefore to grow when the nitrogen reserve of the seed has been exhausted, and the plant turns yellow. If the experiment is interrupted at this stage, no increase of nitrogen can be noted in the plant. If the withered plant is, however, left unremoved, in many cases—though not always—a few nodules are formed by the effective strains here and there in the roots, and the pea pushes out new shoots which begin to grow. According to this experiment, the immunity seems to weaken as the plant withers.

(2) If the seed of the pea is simultaneously inoculated with an effective and an ineffective strain, nodules are formed almost regularly by both strains in the roots. The growth of the plant varies accordingly. The pea may grow as well as after inoculation with an effective strain only, but it may also grow very poorly, depending on which one of the strains becomes dominant. Results between these two extremes are perhaps the most common ones.

The immunity is a somewhat local phenomenon. The pea can be grown in a sterile culture system where the roots by means of a branched tube have entered two separate culture flasks, if then the roots in one flask are infected with an ineffective strain and, after the first nodules have appeared there, the uninoculated roots in the other flask are inoculated with an effective strain, the latter is often, though not always, able to form nodules and the pea begins to grow. If the roots are in the same flask, an effective strain used for later inoculation is never able to form nodules before the withering of the plant, as was already mentioned above.

In microscopic examination of the effective and ineffective nodules the following can be noted: the effective red nodules, round cell formations—no rods—are to be seen. The nodules formed by the ineffective strain H VIII contain, on the contrary, rod-shaped bacteria which seem to be surrounded by a slimy layer. In water, under anaerobic conditions the root nodules formed by effective strains contain rods and branched bacteroid forms. On the basis of these observations and with regard to the peculiar fact that a given strain which forms ineffective colourless nodules on one legume may, in another form effective red nodules (cf. our observations on the effectiveness of a bacterial strain on *Trifolium alexandrinum* and on its ineffectiveness on *Trifolium pratense*)⁵ I have formulated the hypothesis that the cause of the inability of an ineffective strain to fix nitrogen in root nodules is perhaps primarily the slimy layer surrounding the bacteria. It prevents the uptake of oxygen, and at the same time the formation of haemoglobin is inhibited. To what extent this hypothesis agrees with the results to be gained will be seen later.

I am indebted to the Rockefeller Foundation for a grant made at the beginning of the War.

OBITUARIES

Mr. James Young

MR JAMES YOUNG, lecturer in physics at the University of Birmingham, who died on May 28, 1945, aged forty-seven, was born at Dalferf, Lanarkshire. He was educated at Allan Glen's School, Glasgow, and in 1916 proceeded to the Royal College of Science, South Kensington. After a brilliant academic career, Young joined the physics staff at Birmingham in 1920 and worked with one of his former teachers, Prof S W J Smith.

At South Kensington, under the influence of the late Prof A Fowler, Young's interest in astronomy—an interest dating from early boyhood—was enhanced to such a degree that finally it exercised a dominating influence on his professional life. At Birmingham, he was given charge of the University observatory and the teaching of astronomy. Between the two Wars he devoted himself untiringly to the study of the moon, observing a great many occultations and also examining the lunar craters in great detail. These craters specially attracted him, and from his own observations and from results obtained from other sources, he compiled an exhaustive catalogue of positions and diameters. These data he analysed statistically in order to determine the relation between the diameter and frequency of occurrence. This examination convinced him that the meteoric hypothesis of crater formation was untenable.

In addition to his contributions to astronomy, Young did a great deal of work in collaboration with Prof Smith on the crystallographic analysis of the meteoric irons. Because of their well-developed structure, these natural iron-nickel alloys lend themselves well to X-ray and microscopic examination and are peculiarly adapted to the study of one of the most fundamental questions of ferrous metallurgy, namely, the precise crystallographic mechanism of the $\gamma \rightarrow \alpha$ transformation and its relation to the Widmanstätten structure. The matter is one of some complexity but Young's geometrical insight enabled him to solve the problem almost completely. He also played a part in proving that the Neumann

bands, so characteristic of many meteoric irons, are mechanical twins in the kamacite. Young left much unpublished work in this field. In particular, he examined in detail the crystallographic relations between the kamacite and the imbedded rods of rhabdite.

Despite all these activities, Young never lost sight of the fact that he was a teacher. His simple, direct style was much appreciated by elementary students although, perhaps, he himself preferred more advanced work, especially in subjects with a mathematical bias, such as relativity.

As a man, Young was somewhat aloof and silent, but to those who knew him sufficiently well, he was both charming and helpful. Whenever he intervened in any scientific discussion, his accurate knowledge usually gave him the final word. His last illness was borne with the greatest fortitude, and he continued working in his quiet way until very near the end. We admired him above all for his lasting devotion to astronomy, and those of us who knew him well will often think of him as we pass the Observatory on our way up the hill to the University. He leaves a widow and two daughters. A A DEE

WE regret to announce the following deaths

Mr. C. S. Middlemiss, C I E, F R S, superintendent of the Geological Survey of India during 1895-1917, on June 11, aged eighty-five.

The Right Hon. Lord Onslow, G B E, president during 1936-44 of the Zoological Society of London, on June 9, aged sixty-eight.

Major Charles E S Phillips, O B E, from 1929 until this year secretary of the Royal Institution, on June 17.

Mr A. E. Rambaut, formerly of the Colonial Forest Service, Malaya, on June 2.

Miss E. R. Saunders, formerly fellow of Newnham College, Cambridge, on June 6, aged eighty.

Brigadier-General Sir Percy Sykes, K C I E, C B, C M G, well known for his contributions to the geography and knowledge of Persia, on June 11, aged seventy-eight.

NEWS and VIEWS

The King's Birthday Honours List

The following names of scientific men and others associated with scientific work appear in the King's Birthday Honours List.

G C M G: Sir Frank Stockdale, development adviser to the Secretary of State for the Colonies, late comptroller of development and welfare, West Indies.

K B E: The Hon. Sir Herbert Angus Parsons, senior puisne judge, Supreme Court, and vice-chancellor of the University of Adelaide.

Knights: Mr R. G. Allan, commissioner of agriculture, Baroda State; Dr H. H. E. Craster, Bodley's librarian; Prof C. E. Inglis, lately professor of mechanical sciences in the University of Cambridge; Mr W. J. Jenkins, director of agriculture, Bombay.

C M G: Prof A. V. Bernard, late chief Government medical officer, Malta; Mr L. Nicholls, director of the Bacteriological Institute, Ceylon; Dr B. S. Platt, director of the Human Nutrition Research Unit, Medical Research Council.

C I E: Mr J. C. M. Gardner, forest entomologist, Forest Research Institute, Dehra Dun; Lieut.-Colonel Kombar Ramaswami Krishnaswami Iyengar, director, Pasteur Institute of Southern India, Coonoor; Capt (E) W. J. Liffon, chief surveyor, India.

C B E: Mr F. M. Birks, chief engineer, Gas Light and Coke Co.; Capt F. Burnett, commissioner of lands, Jamaica; Colonel H. W. R. Chandler, director of supplies, Gold Coast; Mr S. O. Chivers, honorary technical adviser to the Ministry of Food on fruit and vegetable products; Mr B. Hart, consultant adviser in psychiatry, Ministry of Health; Dr J. W. McDavid, managing delegate director, Explosives Division, ICI (Explosives), Ltd; Mr W. D. MacGregor, conservator of forests, Sierra Leone; Mr D. M. Matheson, secretary of the National Trust; Mr H. C. Smith, chief conservator of forests, Burma; Mr B. R. Wood, conservator of forests, British Guiana.

Prof. Szent-Gyorgyi

PROF SZENT-GYORGYI, the well-known Hungarian biochemist and Nobel prize-winner, has recently visited Moscow at the invitation of the Soviet Government. On May 17, he lectured to the Physiological Society at the University of Moscow on his new work on the chemical composition of striated muscle (*Acta Physiol Scand*, 9, Suppl 25, 1945). From muscle material Szent-Gyorgyi has succeeded in preparing myosin in a crystalline form, and a new protein, isolated by his collaborator, F. B. Straub, called actin. Both myosin and actin have striking properties. Myosin is completely discharged by minimal quantities of potassium. Actin can exist in both globular and fibrous forms, and in the cycle of contraction both forms are involved. The contractile system consists of a combination of these two proteins actomyosin. In relaxed muscle actomyosin is dissociated into actin and myosin. Actomyosin passes into the contracted form in the presence of potassium, magnesium and adenosin triphosphate. Szent-Gyorgyi has demonstrated the contractile properties of this system *in vitro*, and his work provides a mechanical picture which is consistent with all the phenomena of muscle contraction. It is only necessary to assume that in striated muscle there are double rods of actin and myosin, to account for the contraction of living muscle. If the molecules of myosin are spirally arranged around a chain of actin molecules, then contraction, when myosin is discharged by ions, will result in a sudden decrease in the pitch of the spiral. This theory is consistent with microscopic evidence. The familiar cross-striation can be explained by the optical properties of the spiral. For, by rotating muscle fibre under the microscope, Szent-Gyorgyi has observed the apparent travelling of the spiral along the length of the muscle. This work was done by Szent-Gyorgyi in Szeged between 1939 and 1944. When the Germans occupied Hungary in 1944, Szent-Gyorgyi had to go into hiding, and he took a lead in anti-Fascist activities and preparations for the liberation of Hungary. In February 1945 he was liberated by the Red Army. He has now transferred his laboratory to Budapest, and he has accepted chairmanship of the Hungarian Board of Education. Outside his field of research, Szent-Gyorgyi's main interests are the re-education of his nation for peace, and the re-establishment of international scientific relations.

Prof. Ragnar Granit

ON June 29, Prof. Ragnar Granit is to deliver at the Royal Institution the fourteenth Thomas Young Oration of the Physical Society, and his subject will be "The Electro-physiological Analysis of the Fundamental Problem of Colour Reception." The occasion will provide an opportunity for a first-hand account of Prof. Granit's recent studies of the electrical response of the retina, summaries of which appeared in *Nature* of January 2, 1943, p. 11, and June 16, 1945, p. 711. Some fifteen years ago, Prof. Granit was working at the Johnson Foundation of Medical Physics, University of Pennsylvania, on the general problem of the retina as a nervous centre, in these experiments he relied mainly on the subjective observations of flicker phenomena. Later, he worked in Sir Charles Sherrington's laboratory at Oxford, where he investigated and analysed the retinal action potentials which develop on stimulation of the retina by light, in this work his tests were carried out on

the retinae of decerebrated cats. Since then he has held the chair of physiology at the University of Helsinki and is now at the Nobel Institute of Neurophysiology, Karolinska Institutet, Stockholm. The continued refinement of his experimental technique has enabled him to record the responses from individual receptors in the retina and to investigate their variation with wave-length. This work is of fundamental importance to the understanding of the processes of colour perception. The account of Granit's methods is of interest not only in connexion with vision but also in the much wider field of nerve physiology, indeed his studies of the retina now form only a part of his research activities.

Manchester Joint Research Council

THE Manchester Joint Research Council, which is representative of the University of Manchester and the Manchester Chamber of Commerce, has appointed Mr. A. D. Butchart to be executive officer. Mr. Butchart will commence his duties immediately and will be known as Executive Liaison Officer. As the permanent official of the Council, his duties will cover a wide field, in particular, he will be accessible for discussion and will deal with correspondence having specific reference to any problems facing industrialists where scientific information would prove valuable. It will be recalled that one of the objects of the Council is "the encouragement of activities designed to bring science and industry into closer relationship." As a practical move to give effect to this, the Council is creating an Information Service, and Mr. Butchart will be in charge of it. The service will not aim at furnishing scientific answers to problems submitted, but at placing the inquirer in touch with that scientific institution or authority best able to deal with each particular subject. In short, the essence of the service will be to introduce the industrial inquirer to the relevant scientific worker. Mr. Butchart has had a long experience in the oil industry. As a research chemist and in other capacities he has served in Burma, Iran and Iraq. From the outbreak of war to the present time, he has been employed on important Government work. Until a permanent office can be established, contact can be made with the Executive Liaison Officer, c/o The Manchester Joint Research Council, at the Manchester Chamber of Commerce, Ship Canal House, King Street, Manchester, 2.

Scholarships and Research Fellowships in the Textile Industries

TEXTILE MACHINERY MAKERS, LTD., the constituent firms of which are Platt Brothers and Co., Ltd., Howard and Bullough, Ltd., and other textile machinery manufacturers, have established a scheme for the furtherance of higher education and research in relation to the textile industries. It provides for the first instance for the expenditure of £35,000 over a period of seven years, the administration of the funds being vested in a Board of Trustees for the award of scholarships and research fellowships to be known as "The Sir Walter Preston Scholarships and Research Fellowships" and tenable in the Faculty of Technology of the University of Manchester, or in such other university institution as may be from time to time determined.

The scholarship awards will be as follows: Group for works apprentices who have obtained the High National Certificate in Mechanical Engineering (£250

300 a year for three years), Group II, for works apprentices who have obtained the Ordinary National Certificate in a textile or equivalent subject (£225-300 a year for four years), and Group III for secondary school leavers possessing the Higher School Certificate or equivalent qualification (£200-250 a year for three years). The courses to be followed will be in textile engineering, or mechanical engineering, or textile technology, or economics. A small number of scholarships (Group IV, £300-350 a year for three years) will also be offered to honours graduates in science or engineering in order to attract suitable workers into the textile machinery industry or the textile industry. The Trustees are also empowered to award one or more research fellowships which will enable a selected candidate from any of the groups I to IV to continue in advanced study and research for a further period of two, three or four years, with grants of £400-550 a year.

During the first year of the scheme the following awards will be offered: five in Group I, three in Group II, two in Group III, one in Group IV. In succeeding years further awards will be offered of which due notice will be given. In deciding on the scale of assistance to be given under the scheme, the directors of Textile Machinery Makers, Ltd, have been guided by two main considerations: (1) compensation for the sacrifice of freedom to engage in remunerative occupation, and (2) the desirability of enabling all scholars to play a full part in the social, athletic and other extra-curricular activities of university life. All undergraduate scholars will be required to live in one of the university halls of residence, provided there is accommodation available. The award of scholarships in Groups I and II is restricted to candidates nominated by the constituent companies of Textile Machinery Makers, Ltd. The scheme will come into operation for the university session commencing October 1945, and applications addressed to S H L Greaves, Textile Machinery Makers, Ltd, 60 Huddersfield Road, Oldham, were to be submitted not later than June 23, 1945.

National Certificates in Applied Physics

THE announcement by the Ministry of Education of a scheme for the award of Ordinary and Higher National Certificates in Applied Physics brings to fruition one of the recommendations made in the Institute of Physics report on Education and Training issued in 1943. Students may obtain further particulars of the courses from their local technical colleges or local director of education. With a rapid growth of physics in industry and in the different Government services, it has been found that the existing courses in branches of engineering, in chemistry and so on do not singly provide the combination of knowledge required by juniors in some branches of work which depend on the advances of science, such as, for example, the physical testing of materials and the maintenance and use of instruments for the measurement and control of different processes.

The three-year part-time course for the Ordinary National Certificate in Applied Physics must include mathematics, physics and chemistry, and in the first year a special course (not the orthodox engineering one) in workshop practice and drawing. The physics in the course is to be treated realistically and the principles are whenever possible to be illustrated by practical examples drawn from the industries in which the

students are working. The course in applied physics in the final year is to be related to the local industries. Although English is not included formally as a subject in the course, it is a part of the scheme that at all stages and in all classes attention is to be paid to its correct use. It is hoped in this way to help to train students to present written statements which are clear and concise, when in the course of their employment they are required to report on their work. The course for the Higher National Certificate must be a two-year part-time one, and must aim at reaching a standard in the several branches of physics corresponding to that required for a degree in the subject at pass standard. It will include mathematics and a special subject related to the student's daily work in local industry.

Royal Asiatic Society of Bengal

At the annual meeting of the Royal Asiatic Society of Bengal, the following medals and prize were awarded: Joy Gobind Law Memorial Medal, to Rai Bahadur Dr S L Hora, director of fisheries, Bengal, in recognition of his conspicuously important contributions to our knowledge of the ichthyology of Asia; Paul Johannes Bruhl Memorial Medal, to Dr N L Bor, formerly forest botanist, Imperial Forest Research Institute, Dehra Dun, for his important original research in the Gramineae and the ecology of Indian plants; Dr Bimala Churn Law Gold Medal, to Dr D R Bhandarkar, formerly Carmichael professor of ancient Indian history and culture, University of Calcutta, for his important contributions to ancient Indian history and archaeology; Sarat Chandra Roy Memorial Medal, to Dr Verrier Elwin, of the Bhumijana Seva Mandel, Patangarh, C P, for his meritorious and many-sided contributions to the study of cultural anthropology of India; Elliott Prize for Scientific Research for 1944, to Dr S K Chakrabarty, of the University College of Science and Technology, Calcutta (the Prize for 1944 was for mathematics).

The following officers were elected: *President*, Dr Meghnad Saha, *General Secretary*, Dr Kalidas Nag, *Treasurer*, K P Khaitan, *Philological Secretary*, Dr Nalinaksha Dutt, *Joint Philological Secretary*, Dr Mohammad Ishaque, *Natural History Secretaries*, Dr S L Hora (Biology), Dr K N Bagchi (Physical Science), *Anthropological Secretary*, Rev W G Griffiths, *Historical and Archaeological Secretary*, Dr B C Law, *Medical Secretary*, Dr Indubhusan Basu, *Library Secretary*, Dr Nalinaksha Dutt.

International Commission on Zoological Nomenclature

THE International Commission on Zoological Nomenclature announces its intention of publishing at an early date a revised and up-to-date edition (1) of the "International Code of Zoological Nomenclature" and (2) of the "Official List of Generic Names in Zoology". The last edition of the English text of "The International Code of Zoological Nomenclature" was published some years before the War and is now out of date for various reasons, including the adoption by the International Congress of Zoology of changes in some of the Articles in the International Code. The revised edition will consist of the substantive French text (on left-hand pages) and the English translation (on right-hand pages). The volume, which will be fully indexed, will also

contain a detailed analysis of all the "Opinions" so far rendered by the International Commission in regard to the interpretation of the provisions of the Code "The Official List of Generic Names in Zoology" was established by the International Congress of Zoology at its meeting at Monaco, in 1913 for the purpose of recording full particulars relating to the names of the 5,000-10,000 best-known and most important genera in the animal kingdom with their type species. So far, however, only about seven hundred names have been placed on the "Official List", due largely to the fact that the decisions taken by the International Commission have never hitherto been brought together in a single volume and with a full index. It is hoped that the "Official List" will now develop into a powerful instrument for stabilizing zoological nomenclature. It is hoped that its publication in book form will stimulate specialists to make proposals for the addition of other generic names important not only in systematic zoology but also in the applied sciences and in the teaching of zoology at the universities.

The International Commission is anxious to issue each of the above works at the lowest possible price, for it desires that both shall be within the financial means of every zoologist. This will only be possible if, before publication, the Commission is assured of a sufficient volume of immediate sales. Zoologists are accordingly invited at once to register themselves as prospective subscribers. As soon as the publication price has been fixed, a notification will be sent to all such subscribers, who will be granted a discount of 20 per cent on the publication price, provided that payment at the reduced rate is made to the Commission before the date of publication. All inquiries should be addressed to the International Commission on Zoological Nomenclature at its Publications Office, 41 Queen's Gate, London, S W 7.

Globe Lighting

WHAT appears to have been a clear example of globe lightning has been described by Mr B E Waye, "Larch Gates", Altwood Bailey, Maidenhead, Berks. He writes, "At about 2.20 a.m. on May 8, during the height of an intense thunderstorm, I observed a roughly circular orange glow, about the same apparent diameter as the sun, on the horizon, in a southerly direction. The glow was moving towards the west and was followed by a horizontal column of white vapour. It took about ten seconds to reach a point in the south-west, when it disappeared with a flash, the succeeding noise could not be distinguished with certainty from other claps of thunder."

Lady Tata Memorial Trust

THE trustees of the Lady Tata Memorial Fund announce that, on the recommendation of their Scientific Advisory Committee, they have made the following awards for research in blood diseases, with special reference to leukaemia, for the academic year beginning on October 1, 1945. *Grants for research expenses*. Dr P A Gorer (London) and Dr A H T. Robb-Smith (Oxford). *Personal grant*. Dr Penelope K Hammick (Oxford). *Part-time personal grant and grant for research expenses*. Dr W Jacobson (Cambridge). Since these awards do not fully use the margin of funds available, it is hoped to issue a public advertisement for new candidates from the continent of Europe and elsewhere, as soon as conditions permit.

Summer Schools in Health Education

THE Central Council for Health Education will conduct two summer schools in England this year. One will be residential, during August 4-13, at Kingsmoor School, Glossop, Derbyshire, the other will be non-residential, during August 15-29, at Chelsea Polytechnic, Manresa Road, Chelsea, London, S W 3. The Glossop school will be directed by Mrs F A Ogden, and the London school by Mr L J F Brimble. The schools are intended primarily for those who have to do with the training and care of children and young people—teachers, youth leaders, health visitors, school nurses, educational and medical administrators—but would also be of interest to general practitioners. The object of the schools is to review the principles of mental and physical health and development, to discuss the main health problems confronting the individual and the community, and to consider the methods of health education, including sex education. Those wishing to book accommodation or to be supplied with further details about the schools should write to the Medical Adviser and Secretary, Central Council for Health Education, Tavistock House, Tavistock Square, London, W C 1. The Scottish Council for Health Education is holding a residential summer school at the University of St Andrews during August 18-September 1. The directors of the school are Prof Andrew F Skinner of the University of St. Andrews, and Prof A D Peacock, of University College, Dundee. Courses and lectures will be given under the headings of physiology, psychology and social medicine. Further information concerning the Scottish school can be obtained from the Secretary and Treasurer, Scottish Council for Health Education, 3 Castle Street, Edinburgh, 2.

Announcements

UNDER the statute of the Royal Society which provides for the election of persons who either have rendered conspicuous service to the cause of science or are such that their election would be of signal benefit to the Society, the Right Hon. Sir John Anderson, Chancellor of the Exchequer, has been elected a fellow of the Society.

DURING his recent tour in Sweden to lecture on penicillin, under the auspices of the British Council, and at the invitation of the Swedish Medical Society, Sir Howard Florey, professor of pathology in the University of Oxford, was presented with the Berzelius Medal in silver. This Medal was given to members of the Swedish royal family and certain other distinguished persons when it was instituted in 1850 but has not been awarded since that time.

SIR D'ARCY THOMPSON, professor of natural history in the University of St Andrews, has been awarded the Daniel Giraud Elliot Medal for 1942 by the U.S. National Academy of Sciences. The Medal is awarded for distinguished work in some branch of zoology or palaeontology.

A CONFERENCE on "School and Society" will be held under the auspices of the Institute of Sociology at St Hilda's College, Oxford, during July 26-August 3. The president of the conference will be Sir David Ross, whose presidential address is "The Challenge: the Present Crisis and the Needs of the Revolution". Further information concerning the conference can be obtained from the Hon. Organizing Institute of Sociology, Le Play House, Albert Road, South, Great Malvern, Worcestershire.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

Cancelled Visit of British Men of Science to the Academy of Sciences of the U.S.S.R.

MANY readers of *Nature* will have been astonished and repelled by the studied discourtesy with which eight of the intending guests of the Soviet Academy of Sciences were prevented by His Majesty's Government last week from going to Moscow. Not only were they put to gross inconvenience and annoyance by the refusal, without warning and at the last moment, of permission to travel, but also the explanation given was as incredible as the real reason was insulting.

In this prohibited group were those whose talents and devotion have rendered priceless service to the nation during the War. But let us remember the words of the "Preacher"

"There was a little city and few men within it, and there came a great king against it and besieged it and built great bulwarks against it

"Now there was found in it a poor wise man and he by his wisdom delivered the city yet no man remembered that same poor man

"Then said I, Wisdom is better than strength nevertheless the poor man's wisdom is despised, and his words are not heard"

The offensive treatment of our scientific colleagues, unconceivable towards members of most other professions, is a sufficient comment on the patronizing ministerial praise with which science and scientific men are occasionally favoured. When they, and others, are offered reparation later on 'awards' or honours, let them recall the words of T. H. Huxley

"The sole order of nobility which, in my judgment, becomes a philosopher, is the rank which he holds in the estimation of his fellow-workers, who are the only competent judges in such matters"

Distribution of Vanadium, Chromium, Cobalt and Nickel in Eruptive Rocks

WHEN analysing the rock differentiation suite of the Skaergaard intrusion, Greenland, L. R. Wager and R. L. Mitchell¹ found a most interesting distribution of the above trace elements, which are comparatively immobile

TABLE 1 THE SKAERGAARD INTRUSION (EARLY ROCKS MENTIONED FIRST, - THE CONCENTRATIONS CALCULATED AS WEIGHT PER CENT, SPECTRUM ANALYSIS)

	Gabbro-picroite	Olivine-gabbro	Middle gabbro	Horton-olite-ferrogabbro	Late basites, $M(n=3)^*$	Acid granophyre
V	0.010	0.020	0.026	0.004	0-tr	0.0010

Ni	0.012	0.009	0.0075	0	0.0010

TABLE 3 LATE, ABNORMAL DIFFERENTIATION SUITE, EASTERN UPLAND

	Peridotite	Allivalite	Ultra-basic norite	Amphibole-gabbro	Microcline-granite (tr.)
V	0.006	0.0015	0.10	0.035	0.0010
Cr	0.0005	0.00013	0.00020	0	0.00010
Co	0.020	0.006	0.0005	0.0023	0.00005
Ni	0.045	0.012	0.0020	<0.00002	0.00005

Comparing Tables 1-3, it might be assumed that the amounts of Fe + Mg are to be regarded as similar in each member, according to the analyses. We may here point out the striking resemblance between Table 1 and Table 2, whereas the rocks of Table 3 in part display a different behaviour of the actual elements. The problem will be dealt with more fully in a later paper.

Intensities of Light Absorption

It is an interesting and well-known fact that the order of magnitude of the highest extinction coefficients recorded for the absorption of light rarely exceeds $\epsilon \sim 10^5$, where ϵ is the molecular extinction coefficient.

The problem of absorption intensity can be approached in a simple way, as follows. Consider light of intensity I falling on a slice of thickness dl of a cell of unit area filled with the vapour or a dilute solution in a transparent solvent of the absorbent at a concentration of c gm-mol per litre. Let the average effective absorbing area ('chromophore area') of the absorbing molecules in the plane perpendicular to the incident light be a . Then

Illumination falling on absorbing molecules

$$= \frac{\text{Area of absorbing molecules}}{\text{Total area}} \times \text{Total illumination} \\ = \frac{cNadl}{1000} I,$$

and

$$\text{Illumination absorbed} = -dI = F \frac{cNadl}{1000} I,$$

where F will be termed the *light extinction factor* and represents the fraction of the light falling on the absorbing molecules which is absorbed, and N is the Avogadro number. Integrating between the limits $l=0$ and $l=l$

$$\epsilon = \frac{1}{cl} \log_{10} \frac{I_0}{I} = \frac{FNa}{2.3 \times 1000} = 2.64 \times 10^{-20} Fa \quad (1)$$

If a is taken as the largest cross-sectional area ($[a]$) of the molecule and F put equal to unity, (1) yields the maximum possible value ($[\epsilon]$) of ϵ for that molecule. For a simple molecule, $[a]$ is of the order of 10^{-16} cm², hence $[\epsilon] \sim 10^5$.

Both classical electromagnetic theory and quantum mechanics lead to the expression

$$f = \frac{23 \times 10^3 \times mc^2}{N\pi e^2} \int \epsilon_r d\nu \quad (2)$$

for f , the effective number of oscillating electrons or 'mean oscillator strength', where m and e are the mass and charge of the electron, c the velocity of light, N the Avogadro number, ϵ the molecular extinction coefficient and ν the wave number. For an absorption band of normal half-width (c 2,000 cm^{-1}) in the visible and ultra-violet region, $f = 1$ requires^{1,2,3} $\epsilon \sim 10^6$.

The simple treatment outlined above thus yields the same result for the maximum possible value of ϵ as the classical one, but F , unlike f , is an absolute quantity which depends only on molecular size and configuration and involves no assumption as to the mechanism of absorption. The observed values of ϵ_{max} are always smaller than $[\epsilon]$, this can be due to

(1) a being smaller than $[a]$ if, as will generally be the case, the system responsible for absorption in the wave-length region considered does not comprise all the atoms of the molecule, or if, in an optically anisotropic molecule, absorption depends on the spatial orientation of the molecule with respect to the incident light

(2) F being smaller than unity, if the transition does not always occur when a photon of the right magnitude falls on the molecule in the optimum spatial orientation. In classical and in quantum theory, the interaction probability depends on the dipole moment ('transition moment') associated with the transition, but F will also be reduced if only certain electronic, vibrational or rotational states of the molecule represent absorbing entities, or, in a different terminology, if the transition only occurs in certain resonance forms of the molecule. The magnitude of F may be regarded as a measure of the contribution which the resonance form responsible for absorption in the wave-length region considered makes to the 'hybrid' ground state

On the other hand, if F is assumed to be unity or can be otherwise estimated, the effective chromophore area (a) can be calculated from the observed value of ϵ_{max} . In a spherically non-symmetrical molecule the calculated value of a will be smaller than the true chromophore area by a statistical factor due to random orientation

In linear polyene systems⁴ of type $-(C=C)_n-X$, $\epsilon_{\text{max}} \propto n$. If F is independent of n , $a \propto \epsilon_{\text{max}}$, hence $a \propto n$. This requires the most effective incident direction for absorption to be perpendicular to the molecular axis and substantiates the view^{5,6} that the electrons responsible for absorption in the visible and ultra-violet regions of the spectrum are directed in a plane perpendicular to that of the covalent bond.

I am indebted to Dr M. Blackman for valuable discussion.

The Two-body Gravitational Problem in Kinematical Relativity

THE equations of motion of two gravitating particles have been given by Milne¹, they are second-order differential equations in $(t_1, \mathbf{P}_1)$, $(t_2, \mathbf{P}_2)$ the epochs and vector positions of the two particles as measured by a fundamental observer, O. From their derivation, the equations are invariant for Lorentz transformations from one fundamental observer to another. There are eight variables, four for each particle, but only six differential equations—since Milne's equations (45') and (46') may be deduced from (45) and (46). Thus a further relation is needed in order to integrate the equations.

Milne has proposed for this relation the equation $t_1 = t_2$, so that the event $(t_1, \mathbf{P}_1)$ in the history of the particle m_1 , and the event $(t_2, \mathbf{P}_2)$ in the history of m_2 are simultaneous in the experience of O, the relation, as he points out, is not invariant for Lorentz transformations. Schild² has recently suggested that this invalidates the whole treatment, since if the equations are solved with the additional relation $t_1 = t_2$, the orbits obtained will not be invariant.

However, there is no difficulty in finding an invariant relation to replace $t_1 = t_2$, and contrary to Schild's expressed view, there is little or no choice. Since only one relation is needed, it will be symmetric in the suffixes 1 and 2, and it will also be a scalar relation. Only three invariant scalars can be constructed from the two four-vectors, $(t_1, \mathbf{P}_1)$, $(t_2, \mathbf{P}_2)$ namely, $t_1^2 - \mathbf{P}_1^2/c^2$, $t_2^2 - \mathbf{P}_2^2/c^2$, $t_1 t_2 - \mathbf{P}_1 \cdot \mathbf{P}_2/c^2$. There is a further condition that $t_2 \rightarrow t_1$ as $\mathbf{P}_2 \rightarrow \mathbf{P}_1$. The relation suggested by Schild may be written

$$(t_1^2 - \mathbf{P}_1^2/c^2) + (t_2^2 - \mathbf{P}_2^2/c^2) = 2(t_1 t_2 - \mathbf{P}_1 \cdot \mathbf{P}_2/c^2)$$

This is more simply expressed in the form,

$$t_2 - t_1 = \pm |\mathbf{P}_2 - \mathbf{P}_1|/c$$

Taking the upper sign, we see that the effect of n on m_2 is associated with a retarded time, whereas the effect of m_2 on m_1 occurs at an advanced time so that the relation is not truly symmetrical.

The only relation which seems entirely acceptable

$$t_1^2 - \mathbf{P}_1^2/c^2 = t_2^2 - \mathbf{P}_2^2/c^2$$

Putting each side of this equation equal to T^2 , we obtain a simple physical interpretation. The event $(t_1, \mathbf{P}_1)$ is the passing of the particle m_1 and a fundamental observer A_1 , who records the epoch of the event as T , similarly, the event $(t_2, \mathbf{P}_2)$ occurs at a fundamental observer A_2 , in whose experience the epoch is also T . This gives a definition of simultaneity which is invariant, two events are simultaneous in this sense if the epochs assigned to them by the fundamental observers at which they occur are equal.

The actual equations of motion have a remarkable property in that, no matter what relation is assumed between t_1 and t_2 to make the problem determinate they possess an energy integral. Denoting by E_1 , E_2 , the gravitational potential and the kinetic energies of the two particles, Milne has shown that

$$\frac{dE_1}{dt_1} + \frac{\partial \chi}{\partial t_1} + \frac{d\mathbf{P}_1}{dt_1} \cdot \frac{\partial \chi}{\partial \mathbf{P}_1} = 0,$$

with a similar equation for E_2 and t_2 . If t_1 and t_2 are unspecified functions of a single parameter s , the rate of change of total energy with the parameter

$$\frac{E_1}{t_1} \frac{dt_1}{ds} + \left(\frac{\partial \chi}{\partial t_1} + \frac{dP_1}{dt_1} \frac{\partial \chi}{\partial P_1} \right) \frac{dt_1}{ds} + \left(\frac{\partial \chi}{\partial t_2} + \frac{dP_2}{dt_2} \frac{\partial \chi}{\partial P_2} \right) \frac{dt_2}{ds} + \frac{dE_2}{dt_2} \frac{dt_2}{ds}$$

this is zero, independently of the relations between t_1 , t_2 and s . Thus $(E_1 + \chi + E_2)$ is constant for any fundamental observer, no matter what definition of simultaneity he adopts

Milne, *Proc Roy Soc. A*, **160**, 12 (1937)
Schild, *Phys Rev*, **66**, 340 (1944)

I AM in general agreement with the content of Mr Camm's letter. The fact which he independently arrives at, that the energy integral in the problem of two bodies (or indeed, of any number of particles) is independent of the simultaneity convention adopted, I had already encountered in my own work. I may point out here that until some simultaneity convention is adopted, a conservation law applying to a number of different particles has no meaning, for the essence of a conservation law is that we pick out some attribute of the motion of each particle, and add them all together. If these attributes are varying in time, as in gravitational problems, it is essential to decide at what epoch to evaluate each attribute, and so to adopt a standard of simultaneity. It is therefore very satisfactory that the conservation of energy comes out independently of the standard of simultaneity adopted. Similar considerations apply to the conservation of linear and angular momentum, to which I hope to return on a future occasion.

Thermal Stability of D.D.T.

It appears that on certain information obtained from America the belief has become current that D.D.T. decomposes and loses hydrogen chloride at relatively low temperatures, for example, of the order of 107–130°C.

Recently, Fleck and Haller¹ have shown that iron and aluminium compounds catalyse this decomposition very readily at 110–120°C, in 15 minutes to the extent of 99 per cent with the formation of the corresponding dichloroethylene (m.p. 88–89°C). We have now examined the thermal stability of D.D.T., and find that this substance, whether it be pure or of commercial quality, is only decomposed at relatively high temperatures.

We have confirmed Fleck and Haller's observations that metal salts, even in very small amounts, enhance the onset of this decomposition.

Our experiments were carried out by placing samples of D.D.T. in a tube fitted with a thermometer and an air-bubbler, and heating in a glycerine bath. The air was drawn through a short air condenser and passed into 1 per cent silver nitrate solution, acidulated with nitric acid. The sample (c. 40 gm.) was melted at 110–115°C, and the temperature raised at the rate of 1.2–1.4°C/minute. The decomposition point was noted as the temperature at which definite turbidity appeared in the silver nitrate solution.

In sample No. 2, rapid evolution of hydrogen chloride set in with consequent precipitation of silver chloride.

Effect of Pretreatment on the Toxicity of Insecticidal Films on Building Surfaces

INSECTICIDAL films, formed by the deposition of a solution of pyrethrins in a heavy refined mineral oil of very low volatility, for example, Shell Oil P 31, have been used in warehouses for the control of *Ephestia* and *Plodia* moths and caterpillars¹. These films were formed on wooden boxes. There has more recently been a considerable increase in scope for the use of such films for controlling other pests of stored foodstuffs, especially beetles, which are more resistant than the moths and their caterpillars to most insecticides, including the pyrethrins. We have found, however, that, other things being equal, the toxicity of films of pyrethrins in a heavy oil differs widely according to the material upon which the insecticide is deposited.

In laboratory experiments at 25°C and 70 per cent relative humidity, samples of different building materials were sprayed with 1.6 per cent w/v pyrethrins in P 31 oil at a rate of 4 mgm/sq. cm., this deposit is much greater than that applied in practice. Twenty-four hours after spraying, batches of flour beetles, *Tribolium castaneum* Herbst, were confined on the samples. The percentages of insects knocked down and dead after six days exposure to the insecticide are shown in the accompanying table.

Surface	Knock-down (%)	Dead (%)
Rough deal	100	59–77
Brick	100	15–31
Limewashed brick	0–12	0–8
Concrete	0–16	0–16
Cement	0–10	0–10

Thus, oil films incorporating pyrethrins as the toxic agents were of moderate toxicity when deposited on deal, of low toxicity on brick, and virtually non-toxic on limewash, concrete and cement. A trial under practical conditions has confirmed the differ-

THE TOXICITY TO *T. castaneum* OF FILMS FORMED ON PRE-TREATED CEMENT BY 1.5 MG/M² OF 1.6 PER CENT PYRETHRINS IN P 31. INSECTS CONFINED ON FILMS FOR 8 DAYS. PRETREATMENTS: A, SIZE (10 PER CENT), B, GELATIN (5 PER CENT), C, STARCH PASTE, D, POLYVINYL ACETAL EMULSION, E, BRICKWORK SEALING PAINT, F, NO PRETREATMENT.

ence in toxicity between insecticidal films on wood and on limewash.

Ways have been sought to increase the toxicity and persistence of these films. The most striking results were obtained by pretreating the surfaces, before application of the insecticide, with substances which might be expected to reduce greatly the rate of sorption into the substrate, and so to render the insecticide more available to insects walking over the surface. Many substances, including water, hygroscopic materials, sodium silicate preparations, paints, varnishes and colloidal gels were put through preliminary tests to assess their value as pretreatments. The relation between film toxicity and film age was determined for some of the most promising of these when applied to cement. The accompanying graph shows the results. Insecticidal films formed by deposits of 1.5 mgm/sq cm of 1.6 per cent pyrethrins remained highly toxic under laboratory conditions for more than three weeks on some coatings.

After further investigation, size and gelatin, applied in aqueous colloidal solution, have been selected as the most useful of the materials at present available, gelatin was better than size at equal concentration. A solution of pyrethrins was used in most of the laboratory work, but coatings of size or gelatin also supported solutions of other insecticides, including DDT, in an oil base.

A trial of size under practical conditions indicated that it was effective, provided that a continuous coating was formed.

Preliminary Report on the Purification and the Molecular Weight of Hypertensin

DURING an investigation on the chemistry of hypertensin some facts have emerged worth a brief report. Hypertensin has been purified to a very high degree, its effect in raising the blood pressure of a cat under chloralose anaesthesia equalling that of adrenaline. The smallest dose eliciting an appreciable effect on the blood pressure lies in the vicinity of 0.5. Important steps in the ultimate purification are chromatography¹ and electro dialysis.

The former rests upon the fact that hypertensin adsorbed on aluminium oxide from a methyl alcohol solution and eluted with appropriate mixtures of methyl alcohol and water.

For the electro dialysis an apparatus constructed by Hammarsten² was employed. Parchment paper was used as cathodic membrane, and goatskin, which is impermeable to hypertensin, as anodic membrane. It was found that if the reaction in the centre compartment was held more alkaline than pH 7.5 with barium hydroxide, no hypertensin passed into the cathodic compartment. Thanks to this fact, inorganic salts and other impurities could be removed without loss of activity. When thereafter the reaction in the centre compartment was made acid to pH 3 with sulphuric acid, hypertensin rapidly passed out into the cathodic compartment. 1 mgm. of this preparation obtained in good yield (70–80 per cent) had a activity corresponding to 35 mgm. tyramine phosphate. The nitrogen content (Kjeldahl) was 13.6 per cent.

From the last experiment together with earlier electrophoresis experiments³ it was concluded that hypertensin must be neutral or nearly neutral in character. Hence a determination of the diffusion constant at neutral reaction would give information—though approximate—on the molecular weight of hypertensin. The apparatus and technique of Theorell⁴ were used, and the diffusion was followed by activity measurements. To prevent inactivation of hypertensin the experiments were performed at 0°C. In two different determinations the diffusion constant was found to be 1.20×10^{-6} cm²/sec resp. 1.18×10^{-6} cm²/sec. Assuming for hypertensin a specific volume of 0.75, the diffusion constant obtained corresponds to a molecular weight of 2,750.

British and Continental Races of the Starling, *Sturnus vulgaris* L., in Canada

AN account of the differences in timing of the reproductive cycles of the British and Continental races of the European starling has been given by Bullough¹, and the consequent differences in external morphology and in behaviour have been emphasized. It was suggested that these differences, particularly in behaviour, may prevent cross-breeding, and that in any event the two races must be considered as subspecifically distinct.

It was further suggested that a critical test of the separate nature of these races might be obtained from a study of the starling in North America. The species was introduced there on numerous separate occasions before the United States Lacey Act of 1900 prohibited further importations of alien species. It is generally considered, although not proved, that the successful introductions were those of 1890 and 1891 in the Central Park, New York City, and that it was the descendants of these few birds which spread half-way across the continent and north into Canada^{2,3}. From the many descriptions of the habits of these birds in their new home, it was already evident that the Continental race of starling was present in enormous numbers, living a flock life throughout the summer, autumn and winter, and developing the migration habit as in Europe. On the other hand, there was also evidence that the British race was present too. Bissonnette⁴, in Connecticut, discovered starlings with unusually large gonads in winter, and associated with this was the observation of Hicks and Dambach⁵, in Ohio, that there are present in winter many pairs of mated birds which roost, feed and live independently "near cavities where they will nest in the spring". Enlarged gonads in autumn and winter, and a consequent interest in nesting sites, are distinguishing features of the British race of starling.

A study of the starlings present in Ville St. Laurent (near Montreal, Quebec), made during the autumn and winter of 1944-45, has confirmed the presence of both races. In October and November the Continental starling was especially common, ranging the countryside in flocks. These birds had dark beaks, indicating the absence of gonad activity, and associated with this, they were unpaired, uninterested in their old nesting sites, and they roosted communally. In sharp contrast, there were also present smaller numbers of British starlings. These birds had beaks turning yellow at the base, indicating gonad activity, and associated with this they were already paired, and spent much time singing by their old nesting sites. Although they remained all day in the close vicinity of these nesting places, in the evening they joined the Continental starlings in the communal roosts.

Towards the end of autumn, just before the onset of severe weather, the southward migration of the Continental starlings was complete. Consequently, in December and January, relatively few of these birds remained in Ville St. Laurent, and it seemed possible that the few which did so came from even farther north. The majority of the starlings remaining in the neighbourhood were of the British type. By the middle of January, these individuals had beaks almost fully yellow, and their attachment to their nesting sites was further strengthened by the fact that nest-hole roosting in pairs then took the place of communal roosting. The few Continental birds which remained had uniformly dark beaks until the end of January when, in some individuals, the first signs of yellow colour appeared. The birds, however, remained unpaired and continued to roost communally.

When, about the middle of March, the huge flocks of Continental starlings returned to the Montreal district, these birds still had beaks which were partially, or even in a few cases wholly, dark, they were unpaired, and being as yet unattached to nesting sites, they still roosted communally. At this same time, the adult British starlings had fully

yellow beaks, nest-building had begun and copulation was frequently observed.

It is therefore evident that the difference in the reproductive rhythm, which distinguishes these two races of the starling in Europe, has proved sufficiently powerful to preserve their separate identities on the American continent for a period of fifty-five years of the most considerable increase in numbers and the most active spread of the species. All this time the breeding ranges of the two forms have been either identical or have overlapped, a state of affairs which is not apparently found in Europe. However, unless there exists some more positive bar to interbreeding than is provided by the fact that the British starlings pair in early autumn while the Continental starlings do not do so before the late winter and early spring, it seems inconceivable that some mixing of the two races has not occurred. To determine the precise amount would obviously require a large-scale statistical study; but it is already abundantly clear, at least in the neighbourhood of Montreal, that such mixing as may have taken place is inconsiderable.

X-Ray Induced Mutations in the Physiology of *Ophiostoma*

Tatum's and Beadle's¹ investigations on *Neurospora* inspired me to attempt to induce physiological mutations in *Ophiostoma multiannum* (Hedge. and Davids.) by means of X-ray treatment. Normal strains of this fungus grew optimally on a synthetic medium containing glucose, ammonium tartrate, inorganic salts, aneurin (= vitamin B₁) and pyridoxin (= vitamin B₆)². Out of 775 monosporous mycelia which were obtained from X-ray treated ascospores by means of a special procedure³, 12 (that is, 1.6 per cent) differed physiologically. The manner in which they differed is shown in the accompanying table.

Strain No.	Physiological properties
225	Biotin-heterotrophic.
358	Parathiotrophic: able to reduce 4-valent sulphur.
446	" : unable to reduce 4-valent sulphur.
460	Requires uracil; also growing with uridine, cytidine or cytosylic acid
513	Requires adenine; also growing with adenosine or adenylic acid
617	Requires <i>p</i> -aminobenzoic acid.
620	Requires adenine as No. 513
636	Parathiotrophic as No. 446
692	" " " "
829	" " " "
834	" " " "
848	Requires guanine; also growing with guanosine.

The ability of No. 358 to reduce 4-valent sulphur (sodium sulphite) was not transmitted to the following generations. All the other physiological properties however, shown in the accompanying table were heritable. These strains should, therefore, be considered as physiological mutants. *O. multiannum*

being heterothallic and rapidly giving rise to perithecia, it was possible to produce by means of adequate combinations monosporous mycelia possessing two or more of the reported divergent properties in the next or later generations.

Parathiotrophy which was induced in five strains in the present study has so far been observed in Nature solely in Saprolegniaceae⁴ and in certain bacteria⁵. The parathiotrophic strains investigated which were not able to reduce 6-valent sulphur (as sulphate or sulphone) assimilated two-valent sulphur as, for example, sodium sulphide, cystine, cysteine and $\text{CH}(\text{SCH}_3)_3$.

The three strains which required adenine required rather considerable quantities of this purine. These quantities were at least a thousand times larger than the required amounts of aneurin and pyridoxin. The mycelium/adenine-quotient seemed to be equivalent to approximately 100. The action of guanine (on strain No. 848) has quantitatively not yet been extensively investigated. This applies, too, to the action of uracil on strain No. 460, in which also cytidine and cytosylic acid—though not cytosine—are active. In all these cases the indispensability of a certain nuclein compound to a certain strain seemed to be due to the fact that this strain lost the ability to synthesize the substance in question, which is necessary for the formation of essential nucleoproteids, co-ferments, etc.

The two auxo-heterotrophic mutants which were induced, that is, the biotin-heterotrophic mutant No. 225 and the *p*-amino-benzoic-acid-heterotrophic mutant No. 617, required only exceedingly small quantities of the growth-substances mentioned. Biotin was even active in a dilution of 10^{-12} , and *p*-aminobenzoic acid in a dilution of 10^{-10} .

More detailed reports of these investigations will be published in Swedish journals of botany.

Serodiagnosis of Trichinosis by Microscopical Testing with Living *Trichina* Larvæ

DURING the last ten to fifteen years, diagnosis of *Trichina* infection in man (and partly also in swine) has been made easier by the adoption of different methods, based on the immunological response of the organism to the parasite. Particularly, the intradermal and the precipitin test with *Trichina* antigen, both first described by Bachman^{1,2}, have been used in many modifications. Thus, I am employing for this purpose a clear Seitz filtrate prepared from *Trichina* larvæ that had been freed from their cysts by artificial digestion, dried, pulverized and then extracted in physiological saline in the ratio 1:100. Though both these tests are a great help in the diagnosis of trichinosis, they may also fail in very mild cases of this disease, and, on the other hand, unspecific reactions may be obtained in persons not suffering from it.

In January 1941³, I proposed a more delicate and more specific microscopical test depending on the peculiarity of living trichina larvæ at 37° C. of evoking typical precipitates in immune serum. Since then, this new method has been tried with good results in some hundred cases of suspected human or animal trichinosis by Hauge⁴ in Norway as well as by me in Denmark and Sweden (*cf.* Bergwall⁵ and Norup⁶). In this connexion it might be mentioned that during recent years several outbreaks of trichinosis have occurred both in Norway and in Sweden, while no cases at all have been reported in Denmark and in Finland.

BUBBLE-LIKE PRECIPITIN REACTION OF IMMUNE SERUM AGAINST LARVÆ OF *Trichinella spiralis*, AFTER 24 HOURS INCUBATION AT 37° C. SERUM SAMPLE FROM PATIENT D.A., 23 DAYS AFTER HIS FALLING ILL. $\times 80$.

For the microscopical test, well-coiled *Trichina* larvæ are needed, which, after having been freed from their cysts by artificial digestion, are very carefully washed with sterile saline. For each test about a hundred larvæ are placed in the depression (diameter 20 mm.) of a sterile, 3.5 mm. thick hollow-ground slide and then covered with 0.5 c.c. of the twice centrifugized serum. A large sterile cover-slip (24 mm. $\times$ 32 mm.) is laid over the serum, care being taken that no air bubbles pass in. The slides are collected on a wire-netting lying in a large rectangular glass dish. Below the wire-netting, wet filter-paper is spread on the bottom of the dish to prevent desiccation of the preparations. The dish is then covered with a glass lid and kept in an incubator at 37° C. The samples are examined under the microscope after five as well as after twenty-four hours.

After five hours the larvæ are very motile. In case the serum is positive, bubble-like or finely granular precipitates are seen primarily around the anterior ends of a greater or smaller portion of the worms. After twenty-four hours the larvæ are often shrunken, an observation made both in normal and in immune serum. Most precipitates are now lying free in the serum. The quantity and form of the precipitates are very variable and highly dependent on the age and size of the infection. As a rule, the reaction becomes positive between the tenth and twentieth day after the appearance of the first symptoms of the disease, which most frequently are oedema of the lids and fever. In a few cases, however, a faint reaction was obtained before the tenth day. In mild cases the antibodies seem to disappear again about a year after the patient's recovery.

Altogether, I was, by aid of the microscopical test, able to ascertain the clinical diagnosis of trichinosis in eighty patients from five different outbreaks, while in thirty other patients, clinically suspected to suffer from trichinosis, this possibility could be excluded. The test proved often to be more sensitive and more specific than the usual intradermal and precipitin tests with trichina antigen. Similar reliable results were obtained in trichinized animals, as pigs (positive already seventeen days after infection), dogs, cats, silver foxes, rabbits and guinea pigs. Necessary conditions for obtaining a clear result even in cases of very light infections are cleanness and sterility of the serum examined.

Pharmacological Action of Cyanic Acid

In the course of a study designed to investigate whether some substances known, or believed to be present, in the body, had any hypnotic action, or could contribute to bring about the internal milieu for example, water-shift) known to prevail during normal sleep¹, a marked pharmacological action of cyanic acid was found.

K M Birch and I found that sodium cyanate was well tolerated by rats, guinea pigs and rabbits in doses which produced marked drowsiness and prolonged sleep. Part of the cyanate used in this investigation we prepared from urea, we are also indebted to Glaxo Laboratories, Ltd, for a gift of pure sodium cyanate. The sleep effect produced is most evident in rats. Though the action is definitely a hypnotic one, no full anaesthesia could be produced. The L D 50 (albino rats of 80-120 gm) is of the order of 30 mgm/100 gm. Rats survived, though with increasing drowsiness, daily injections of 10 mgm/100 gm for three weeks. When the injections were stopped, the rats' behaviour soon returned to normal. No gross pathological sign could be detected in the animals. The blood sugar was normal in rabbits after two weeks of daily injections 10 mgm/100 gm, though higher doses given intravenously were followed by a small and transient rise. The body temperature showed a significant and transient fall of as much as 2°.

The hypnotic action of the drug is diminished by hyroxin and insulin. For adrenalectomized rats the drug was of greatly increased toxicity. Posterior pituitary extracts markedly increased the length and depth of sleep caused by the drug. This, however, seems to be a general effect of posterior pituitary extracts and is also evident with other narcotics (barbiturates, etc).

In more than fifty human volunteers doses of -400 mgm, taken orally, were well tolerated. The only feeling reported by the great majority was tiredness and drowsiness, which was often followed by a short and deep sleep. In many subjects we

observed a distinct miosis shortly before the tiredness was mentioned.

R Bader and I tried to investigate whether cyanic acid is a normal constituent of the body. This was claimed by Montgomery², whose findings, however, we are unable to confirm. Concerning the fate of injected cyanate in the body, a reduction of cyanate to cyanide seems extremely unlikely, because of the low toxicity of cyanate. Moreover, we could not detect, even with the most sensitive reactions (one³ with an identification limit of 0.25 γ), any trace of cyanide in the blood and tissues of animals receiving large doses of cyanate over different periods of time.

The cobalt-acetate colour test for cyanate was negative in brain, liver and muscle, but often positive in kidney extracts of animals receiving cyanate injections.

Cyanate was found not to react with either oxygen or reduced haemoglobin, but it forms a new compound with methaemoglobin. I am greatly indebted to Prof R A Morton, Department of Biochemistry, University of Liverpool, for allowing me to make use of his spectroscopic equipment, and for his invaluable help in constructing the absorption spectrum of cyanate-methaemoglobin, shown in the accompanying figure.

"High Frequency Transmission Lines"

In the review of my recently published book of this title, the reviewer¹ remarks "He [the author] gives only cryptic indication of what is actually achieved by the use of high-frequency transmission lines, and evidently expects that his readers should be satisfied to plunge into abstract study without being tempted by a recital of practical achievements."

I do not disagree with this remark, but must state in reply that considerations of national security made a fuller statement on recent practical achievements impossible, and inevitably my treatment of the subject suffered.

RESEARCH ITEMS

Some Interesting Radulae

YOSHIO KONDO, in his paper "The Dentition of Six Syncerid Genera Gasteropoda, Prosobranchiata, Synceridae (Assimneidae)" (*Occasional Papers Bernice P Bishop Museum, Honolulu, Hawaii*, 18, No 23, 1944) describes the radular teeth of certain land shells described by C Montague Cooke, jun and William J Clench ("Land Shells (Synceridae) from the Southern Western Pacific", *Occasional Papers Bernice P Bishop Museum*, 17, No 20, 1943) *Electrina succinea* (Sowerby), and *Rapanella andersoni* Cooke and Clench were both found in the small island of Rapa but in distinct areas of distribution. The genus *Garretia* is limited to Cook Islands, the radula of *G. brangulata* (Pease) being dealt with here, *Fryanella calcephala* Cooke and Clench comes from Lau Islands, *Quadrassella mucronata* Moellendorff from Guam, Marianne Islands. All these have a very peculiar operculum characteristic of each species and differ much in form of shell. The type of radula is found to be remarkably uniform for all six. There are no lateral processes, and the teeth themselves are peculiar and distinctive in form.

Manganese Content of Fruit Tree Foliage

DIFFERENT crops vary greatly in their susceptibility to manganese deficiency, and although manganese deficiency symptoms have been recognized in the leaves of apple, apricot, cherry, peach, plum (prune) and walnut (as well as in other crops), prunes remain healthy in locations where peaches develop severe manganese-deficiency chlorosis. These differences may be due to differing manganese requirements or to variations in the ability to absorb manganese or to a combination of these factors. Of interest in this connexion are data presented by E. Epstein and O Lilleland (*Proc Amer Soc Hort Sci*, 41, 11, 1942). They report that different fruit trees, when grown under identical conditions, with manganese supplies adequate, have widely different contents of manganese in the leaves. Expressed as parts per million of dry matter of leaves the manganese contents found were for: filbert, 494, walnut, 246, almond, 96, apple, 81, prune, 73, peach, 66, pear, 63, and cherry, 62.7. Clearly, susceptibility of the peach to manganese deficiency is not due to an inability to absorb manganese as the peach leaves contain almost as much manganese as those of the 'resistant' prune.

Ascorbic Acid Content of Tomato Fruits

G B Reynard and M S Kanapaux (*Proc Amer Soc Hort Sci*, 41, 298, 1942) find that two small-fruited tomato species (*Lycopersicon peruvianum* (L.) Mill. and *L. pimpinellifolium* (Jusl.) Mill.) have a much higher content of ascorbic acid than the various types of *L. esculentum*. The ascorbic acid content of the fruits of *L. peruvianum* varied between 58.9 and 63.0 mgm per 100 gm and of *L. pimpinellifolium* between 35.9 and 47.0 mgm per 100 gm. Intermediate sized types, for example, *L. esculentum* var. *cerasiforme* (Dun.) A. Gray (cherry tomato) and *L. esculentum* var. *pyriforme* (Dun.) C. H. Mull (pear tomato) gave fairly high values, but large-fruited commercial types of *L. esculentum* gave low values (11.2–21.5 mgm per 100 gm), while within each type fruit-size and ascorbic acid content showed a negative correlation. Possibly connected with this inverse relation between fruit size and ascorbic acid content are the high ascorbic acid values which have been re-

ported for the fruits of tetraploid tomatoes, as these often have characteristically small fruits (E. C. Stan and R. K. Showalter, *Proc Amer Soc Hort Sci*, 40, 383, 1942).

Tertiary Igneous Rocks of Eastern Otago

FOR many years W. N. Benson has been making a detailed study of the Tertiary igneous rocks of eastern Otago and their tectonic environment. Five papers embodying the results to date, have recently appeared (I, *Trans Roy Soc N Z*, 71, 208 (1941), II, 72, 85 (1942), III, 72, 160 (1942), IVA, 73, 116 (1943), IVB, 74, 71 (1944)). These make a very notable contribution to the geological history, petrology and geochemistry of an extensive area centred on Dunedin. In I and II Prof Benson recognizes (a) a relatively stable region in the west, almost devoid of late Tertiary igneous rocks, though containing in the extreme north-east a great development of pillow lavas and minor intrusions of early Tertiary age, (b) a moderately deformed belt between (a) and the coast, which contains most of the rocks so far described in these papers, and (c) a strongly deformed Central or Dunedin area with Pliocene volcanic rocks belonging mainly to the basalt-trachyte and basalt-phonolite suites, these are to be described comprehensively later. II includes a summary of all the known outlying representatives of the Pliocene petrographic province from regions (a) and (b). A conspicuously differentiated sill of olivine-thermite in this group is described in detail in III. The distribution and geological setting of the Mid-Tertiary basalts, tholeiites and dolerites is dealt with in IVA, while IVB is concerned with their petrology. A special study of siliceous xenoliths and their reactions is promised in a forthcoming paper, IVC. In IVB special attention is given to the pyroxenes and the conditions governing their crystallization. The term 'subcalcic augite' is suggested for pyroxenes between pigeonite ($2V$ up to 30°) and augite ($2V < 45^\circ$). A wealth of optical detail has been provided by F. J. Turner and C. O. Hutton. The average Otago Mid-Tertiary magma corresponds closely with that of the quartz-dolerites of Scotland and the north of England, but the average Pliocene magma is considerably more alkaline and resembles that of the Lower Carboniferous province of the Midland Valley of Scotland.

The Gulf Stream and the Weather in Europe

J. W. SANDSTROM (*Ark. Math. Astron. Fys.*, 30, No 18, 1944) discusses the influence of the Gulf Stream on weather in Europe. It has been generally assumed that heat from the Gulf Stream is disseminated to the surrounding land by winds that have blown over it and are warmed. Sandstrom points out, however, that as the winds are mainly directed towards the Gulf Stream, the warmed ascending air over it being replaced by cooler air blowing from both sides of it, they cannot disseminate heat from it. The winds directed towards the Gulf Stream are deflected about 60° to the right by the rotation of the earth, their direction being from the south or south-south-west over Europe, and from the north or north-north-east over Greenland, and hence the heat produced in Europe and the cold produced in Greenland by the Gulf Stream are greater the warmer the Gulf Stream is. On the way from the tropic to the Arctic, the Gulf Stream loses a considerable amount of heat to the air and colder waters, and in order to transport any heat to the Arctic it must

convey a certain mass of water per second. The speed of the Gulf Stream was probably reduced in 1939, and hence it lost its power to produce low air pressures in the North Atlantic and southerly winds over Europe, hence the winter of 1939-40 was just as cold in Europe as in Siberia, Alaska and Greenland. The cooling of water in the Arctic, increasing its specific gravity, would cause it to sink and the surface water to set in from warmer regions, thus re-establishing the propelling force of the Gulf Stream and increasing its speed. Its waters advance rather slowly, thus in the winter of 1941-42 its warm front may not have reached farther than the south-west coast of Norway. This winter was, therefore, cold, but by the winter of 1942-43 the warm front had passed Scandinavia on its way to the Arctic, the direction of the winds over Europe became more southerly, and the winter was warm over Europe and cold over Greenland. It is suggested that a study of the Gulf Stream properties should make it a suitable medium for long-term weather forecasts.

Economics of Transformer Losses

In a paper recently read before the Institution of Electrical Engineers in London, W. Szwander discusses the valuation and capitalization of transformer losses, outlining a simple and comprehensive procedure for the practical application of the principles of economic selection of transformers. Two aspects are considered: one relating to purchase and the other to the designing of transformers to satisfy specific economic requirements in individual cases. Formulae are developed and supplemented by practical information on the selection of the correct values for the requisite coefficients. A statistical survey is made of methods used by different buyers for the capitalization of the transformer losses. Finally, approximate values of the coefficients in the formulae for the capitalization of losses are suggested, these may be used in the absence of more precise information. Of the two equivalent methods available for making an economic selection of transformers, namely, the comparison of the total annual operating costs and that of the total investment cost including the capitalized value of the losses, the first is the more popular and comprehensive. The more complicated problem of finding the most economic design of transformer to meet given operating conditions is analysed in detail. It is concluded that the economic choice of the loss ratio must be such as to ensure the annual costs of the iron and copper losses being equal, the total losses being fixed so that their total annual cost shall be about 2.5 times the total annual capital cost.

Antispasmodics

TWENTY-EIGHT basic-alkyl esters of substituted α -thienylhydroxyacetic, $C_6H_5S-CH(OH)-COOR'$, and substituted α -thienylacetic acids, $C_6H_5S-CH_2COOR'$, prepared by F. F. Blicke and M. U. Tsao (*J. Amer. Chem. Soc.*, 66, 1645, 1944), in which the substituents R' were such groups as methyl, cyclohexyl, benzyl, phenyl, p -xenyl, α -naphthyl and α -thienyl, and the basic-alkyl groups R' were β -diethylaminoethyl, 3-morpholinomethyl, β -piperidinomethyl, γ -diethylamino-propyl and γ -dibutylaminopropyl, were examined for antispasmodic activity. In general, the activity of the esters of hydroxyacetic acids on the isolated intestinal strip which had been stimulated by acetylcholine was much greater than that of the esters of

acetic acids, and some esters, especially those containing a cyclohexyl group, were equal to, or greater than, atropine in activity, a potency seldom found hitherto in synthetic antispasmodics.

Action of Sulphanilamide on Pepsin, Rennet and Urease

In a third communication on the mechanism of the action of sulphanilamide, read before the Academy of Athens (meeting of Feb. 10, 1944), N. Klissimis has examined the influence of sulphanilamide compounds on pepsin, rennet and urease. Prof. Klissimis finds that the digestion of egg albumin in pepsin solution is retarded by 'Prontosil soluble'. The clotting of milk is also retarded by 'Prontosil soluble', if the experiment is carried out in the presence of a pepsin solution and calcium chloride solution. For the work on urease, the latter was prepared according to the Van Slyke and Cullen method. The pH of the solution was stabilized with a mixture of phosphates at 7.0. The decomposition of urea was measured by the amount of ammonia developed by the reaction. This reaction was retarded in presence of sulphanilamide ('Prontalbina'). Sulphanilamide ('Prontalbina') was also effective in retarding ammoniacal decomposition of urine, the pH of this urine was very little changed.

Data on Meteors

UNDER the title, "An Analysis of British Meteor Data. Part 2. Analysis" (*Mon. Not. Roy. Astro. Soc.*, 104, 257, 1945), J. G. Porter concludes his investigations on the subject (see *Nature*, 152, 420, 1943). After a brief description of the method of classifying and grouping the material for analysis, Porter discusses the errors and their correlation and shows that errors of different kinds—sliding errors, magnitude errors and timing errors—tend to increase with the length of the path of the meteor and also with its brightness. It is not easy to explain this correlation, though in the case of magnitude errors it is suggested that the brighter the meteor the further the observer has to go for standards of reference, and for meteors of planetary brightness or more, these are usually recollected standards only. Adhering to the rules of statistical analysis, it is shown that no essential difference exists between the data for shower and non-shower meteors. In addition, the heights of comparable groups are the same and the 'seasonal effect' is merely of a statistical character. Hoffmeister's assumption of a uniform distribution of meteor paths in space is shown to be without any justification, and the non-distribution of meteor directions is responsible for the apparent seasonal variations on heights. An interesting point appears in Table VIII. There it is shown that the average shower meteor appears and disappears at greater heights than does the average sporadic meteor, a fact which Opik noticed, but the groups are drawn from very different ranges of elongation of the radiant from the apex of the earth's way, and here previous investigators have been misled. Further conclusions are that the low speeds derived from double or triple observations are real, meteors suffering some retardation by atmospheric resistance before they become visible, and that hyperbolic velocities seldom or never exist. The analysis has given the *coup de grâce* to many of the conclusions of the Arizona Meteor Expedition, and, it is hoped, has finally settled the question regarding so-called 'hyperbolic velocities', establishing beyond dispute that meteors are members of the solar system.

SIGNIFICANCE OF HYDROCARBON OILS IN CHEMICAL INDUSTRY

THE Cantor Lectures on "Organic Chemicals from Petroleum", which Sir Frank Smith delivered before the Royal Society of Arts during April, were happily timed to provide the background for wide appreciation of the importance of the recommendations of the Report of the Hydrocarbon Oil Duties Committee*, which Sir John Anderson stated in his Budget speech on April 24 he proposed to accept. The Committee, over which Sir Amos Ayre presided, was appointed by the Chancellor of the Exchequer and the Minister of Fuel and Power, as indicated in last year's Budget speech, and Sir John Anderson has now included in the Finance Bill a provision freeing from Customs duty imported hydrocarbon oils used as raw materials for chemical synthesis. Provision is also to be made for an allowance of an amount equal to the Customs duty in respect of indigenous oils used in these processes, in order that the competitive position in respect of home-produced materials should not be worsened by this change.

The Ayre Committee was appointed at the end of July 1944 "to consider and report upon (a) the effect of the hydrocarbon oil duties on the supply of raw materials to, and the development of, the chemical industry in this country so far as the use of hydrocarbons and their derivatives is concerned, and (b) the extent to which any change in those duties would affect industries engaged in the production of similar products from coal." "Chemical industry" in these terms of reference includes the producers of transformation products, such as dyes, pharmaceuticals and plastics, but excludes the industries using hydrocarbon oils as solvents only, though reference is made to the solvent-user position. Similarly, it excludes the industries concerned with the production of synthetic motor fuels and lubricants, although the Committee considered the influence of developments in this field on other modern synthetic chemical processes.

Reviewing first the effect of the duties on the chemical industry in this sense and its development, the Committee points out that while the visible direct effect of the hydrocarbon oil duties has not hitherto been large, apart from the use of petroleum oils for the manufacture of such products as wetting-agents and detergents, and of turpentine for the manufacture of so-called 'synthetic' camphor, the indirect effect has been considerable. This repercussive effect is due to the protection of indigenous oils and to the fact that benzole, one of the main hydrocarbon raw materials of the existing chemical industry, is in demand as a blending constituent, owing to its high anti-knock value, in the motor-fuel industry, where its value is regulated by that of imported duty-paid spirit. The annual cost to the chemical industry, on its pre-war consumption of 10 million gallons, which may well be exceeded after the War, is thus about £375,000 or about 1d per lb on benzole.

The consequent effect on the cost of chemicals derived from benzole depends on the yield and on the number of steps in the chemical synthesis, and may be more or less than 1d per lb on the primary intermediates. Even where the effect is less on products further removed from benzole, for example, 0.2d on some finished dyes, the increase is significant

and often serious in the export market. The Committee received evidence of the curtailment of the output of certain dye intermediates owing to the almost complete loss of the export trade resulting from this position.

Moreover, as the report notes, the organic chemical industry stands at the opening of a period of great expansion. Chemicals are increasingly providing the basic raw materials of major industries such as synthetic textiles, synthetic rubber and plastics. Since Britain possesses neither the large supplies of hydrocarbons which exist, for example, in America, in the form of natural petroleum, nor the large numbers of scientific and technical personnel trained and experienced in development work, a great effort will be called for to enable her to play a considerable part in the new industry. It is accordingly imperative that the basic and intermediate raw materials should be made abundantly available and that the industry should be free to choose the best material for each particular process or synthesis, guided only by scientific and technical considerations. Since many of the new processes utilize materials derived in part from oil and in part from coal, the growth of the chemical industry based on petroleum may also increase the demand for raw materials derived from coal, and effect of the duties may be far greater in the future, as they will tend to stifle the large-scale production of the primary and basic intermediates.

For these reasons the Committee unhesitatingly accepts the claim that the chemical industry should be able to choose its hydrocarbon raw materials free from the direct and repercussive effects of the present hydrocarbon oil duties, and the industry takes the view that it is urgently necessary that it should be relieved of this encumbrance. The Committee was also impressed by evidence of the extensive use made of the solvent properties of hydrocarbon oils in extraction processes in the industry, while its conclusion is reinforced by its survey of petroleum as a source of chemical raw materials. While the duty on heavy oil has not had any clearly recognizable effect on such developments, the duty at 9d a gallon on light oil has, and there is real danger that if the present position is maintained certain lines of development may be entirely suppressed. For example, the development of 'specialty' refining to provide the gaseous hydrocarbons, particularly the olefins containing one to four atoms of carbon in the molecule, which are the most important raw materials of the new industry, by cracking selected fractions of petroleum oils, and, by the use of aromatization processes, benzene and other aromatic hydrocarbons, will depend largely on the fiscal position. All witnesses from the oil industry urged that hydrocarbons used in the production of chemicals should be freed from duty in order that development should follow the soundest lines without being subject to artificial diversion.

A further consideration which greatly impressed the Committee was that the free growth of new industries producing and using the hydrocarbon raw materials would result in the development of new alloys, apparatus, equipment and technique which will benefit industry generally. Equally, a field would thus be provided for training chemical engineers and metallurgists, the benefit of whose experience is likely to be widely felt in many industries. The question of home refining involves considerations which lie far outside the Committee's terms of reference, but since the quantity of oil required by the chemical industry

* Cmd 6615 H.M. Stationery Office April 1945 3d net

is very small in proportion to total oil requirements, there is, as the Committee points out, no reason why home-produced oil should not play its due part in the new developments, provided the manufacturer is free to use, unaffected by duties or their repercussions, the material most suitable for his purpose.

It is, of course, to this section of the report that Sir Frank Smith's lectures are most relevant, and the importance of the matter is well shown by some of the figures quoted by Sir Frank Smith. To-day, he said, some two hundred chemicals are made on the commercial scale from petroleum raw materials, the annual value of which he estimated at about £200 millions, and in the plastics industry the ratio of petroleum derivatives to non-petroleum derivatives as raw materials is steadily increasing. By cracking processes there are already produced 60,000 tons of ethylene for the plastics industry and 120,000 tons for ethyl alcohol. The actual volume of refinery gases in the world is about 300,000 million cubic feet per annum or 15 million tons, and acetylene is already being made from petroleum and production may be on a very large scale in the future.

Sir Frank Smith contended that there is no antagonism between the coal-chemical industry and a petroleum-chemical industry, and this contention is borne out by the third section of the Ayre Committee report, dealing with coal as a source of chemical raw materials. Surveying first the low-temperature and high-temperature carbonization processes, the Committee concludes that the producer of indigenous hydrocarbons cannot and should not be called upon to bear the cost of reduction in price of his products to the chemical industry, notwithstanding that the protection afforded in 1938 to encourage the production from indigenous materials of fuels for the internal combustion engine had raised the price of certain raw materials to the chemical industry. Considering next the three chief processes for treating coal which yield raw materials for the organic chemical industry—hydrogenation, the Fischer Tropsch process for hydrocarbon synthesis (which has not yet been operated in Britain), and the production of calcium carbide—the Committee finds it difficult to forecast the part which these processes will play in the development of the chemical industry, but believes that it will not be large in the immediate future, and that its recommendations will not impede their development.

The Committee recommends accordingly that chemical manufacturers be allowed to receive without payment of duty (or upon drawback), as raw material for chemical synthesis, any imported hydrocarbon oil, and the Chancellor of the Exchequer, as already noted, indicated his intention of amending appropriately Section 2 of the Finance Act, 1934. In respect of hydrocarbon oils produced from indigenous material and received by a chemical manufacturer as raw material for chemical synthesis, the Committee recommends payment to the manufacturer of an allowance equal to the duty payable on the importation of like oils. Similarly, any producer or refiner of indigenous oils who uses such oils for the production of hydrocarbons for use in the refinery as raw materials in chemical synthesis should also receive an allowance equal to the duty payable on the importation of like oils. On the basis of the pre-war consumption of indigenous hydrocarbon oils by the chemical industry, the total cost of implementing the Committee's recommendations is estimated at something less than £400,000 a year.

In announcing his acceptance of these recommendations, the Chancellor said that many believe that synthetic chemical processes will be of rapidly growing importance in manufacture, and will affect industries outside the field of synthetic chemistry. Research on these problems has been active in several countries during the last five years, and he said he hoped that the gift he was able to make towards the cost of research by this concession will help Britain to establish itself quickly in a worthy position in relation to these new developments. While the Ayre Report does not cover the whole field—and it may well be desirable to examine the wider question of home refining in relation to national economic policy—when read with the Cantor Lectures of Sir Frank Smith, it shows conclusively that we can no longer be content to treat oil questions only as matters of Imperial defence. Equally it endorses the argument of the Parliamentary and Scientific Committee for an adequate examination of our whole policy of the utilization of our coal resources. The prompt acceptance of the Committee's recommendations is a further indication of official recognition of the importance of scientific and industrial research, and a disposition to accord scientific and technical factors their due weight in the determination of policy.

RUSSIAN PHYSICS JOURNALS

FOR a time, when transport between the U.S.S.R. and Great Britain was very difficult, the flow of scientific journals almost stopped. Recently a fairly regular exchange has been re-established. The following notes on physics journals may help those readers to whom the facilities of the London libraries are not readily accessible, but who nevertheless wish to know how physics has fared in the U.S.S.R. in recent years. On first thoughts, a knowledge of the Russian language may seem essential, but realizing the severe difficulties of their language the Russians for more than ten years have been publishing foreign editions, in German, French or English, of some of their journals. Attention will be confined almost entirely to such journals.

The earliest journal of special interest to physicists appears to be the *Physikalische Zeitschrift der Sowjetunion*, published at the rate of two volumes each year starting in 1932. Although most of the papers are in German, some papers are in English. Next to be started was *Technical Physics of the U.S.S.R.*, founded in 1934, having papers in English, German or French. By 1939 the fifth volume had been reached with a publication rate of about twelve parts a year. The centre of publication was Leningrad. In the first volume the editor, A. Joffe, explains that before the Revolution there was practically no technical physics in Russia. By 1934 a number of institutes giving their attention to immediate problems in technical physics had been established. Joffe lists them in seven groups: (1) a group of physical-technical institutes including four Leningrad institutes, Kharkov, Ural, Siberia, Dnepropetrovsk and the Physical Agronomical Institute—with one thousand workers, (2) the Optical Institute—with four hundred workers, (3) the All-Union Electro-Technical Institute with one thousand workers, (4) the Power and Thermal Institutes, (5) the Central Radio Laboratory, (6) the Metallurg-

ical Institutes, and (7) the Institute of Applied Mineralogy and others. At that time there were about three hundred technical scientific publications in Russian. The scope of the journal can be seen from the editor's list comprising (1) electron physics, dielectrics, high-voltage technique, high-frequency physics and gaseous discharge, (2) mechanical testing of materials and structure analysis, (3) thermal technology, (4) applied optics, including illumination, photography and electro-physics, (5) technical acoustics, and (6) high-vacuum physics. Scientific workers of all countries are invited to contribute papers and the editor concludes "We hope that our journal will help to eliminate the language difficulty which prevents foreigners from becoming acquainted with our work and will form yet another link in the chain drawing science and scientists of all countries together." Under the heading 'Bibliography', detailed summaries in English are sometimes given of papers appearing in Russian in other Russian journals.

In 1939, on the basis of the experience gained in publishing these two journals, the Physical and Mathematical Department of the Academy of Sciences decided to replace them by a single journal, the *Journal of Physics*, published from Moscow with S. I. Vavilov as editor. The papers were to be in English, French and German and to include all branches of physics whether theoretical, experimental or technical. The cover bears the portrait of the first Russian physicist, M. V. Lomonosov (1711-65), who was also the first to combine scientific research work with the solution of practical and economic problems. Outside contributions are invited. "We gladly offer the pages of our journal to foreign scientists who would be willing to publish their works through the medium of the *Journal of Physics*." Parts are issued monthly at the rate of two volumes each year. Fittingly the first two papers to appear are by Prof. P. Kapitza on an "Expansion Turbine Producing Low Temperatures Applied to Air Liquefaction" and "Influence of Frictional Forces on the Stability of High-Speed Rotors." The other two papers completing the first part are by A. Filippov and co-workers on "Disintegration of Atomic Nuclei of Cosmic Rays" and "Fluorescence of Aqueous Solutions of Rare Earth Salts." The last two parts of the first volume were issued together, dealing chiefly with work of L. I. Mandelstam and his collaborators and pupils, with a special article in celebration of his sixtieth anniversary. A language analysis of the first volume shows forty papers in English and five in French. The second volume has thirty-six papers in English, two in French and three in German.

At one time statements were made giving the impression that Russian physicists had to devote the whole of their attention to subjects of immediate practical use. There is no justification to be found in this journal for such statements of 'short-sighted policy'. For example, in the analytical index to volume 4, it was necessary to provide entries for the following subjects representative of all the main branches of physics: acoustics, cosmic radiation, crystalline state, dielectrics, discharge of electricity in gases, electrical conductivity, electrolytes, electromagnetic theory, electronics, Hall effect, ionization, ionosphere, liquids, luminescence, low temperatures, magnetic properties, quantum mechanics, methods, machines and instruments, nuclear structure, optical constants and properties, optical theory, photoelectric effect, radiation, radio, scattering of light, scattering of particles, spectra (molecular), super-

conductive state, thermal conductivity, vibration theory. From volume 6 onwards, the editor has been P. L. Kapitza, with E. V. Shpolsky as vice-editor. In volume 5 a new feature was started in giving a list of contents of Russian physics journals, including the titles in Russian and English, but "only those articles whose translations are not published in the *Journal of Physics*." All bibliographical details of the original Russian journals from which the full translations are made are unfortunately omitted. In format, style and content, the *Journal*, which is now being received regularly in Great Britain, is very similar to the *Physical Review*. The majority of papers are in English, with a few in French or German.

The remaining physics journals are published entirely in Russian. Recently the practice of giving also a title index and summary in some other European language has unfortunately stopped. Copies are, however, being received in Britain of several other journals of special interest to physicists. *Acta Physicochimica URSS* is similar in content to the *Transactions of the Faraday Society*, and is published almost entirely in English with occasionally a paper in French. Each volume consists of six issues and by 1944 the nineteenth volume had been reached. The chief editor is Prof. A. Frumkin, Bolshaya Kaluzhskaya 31, Institute of Colloid- and Electrochemistry, Academy of Sciences of the U.S.S.R., Moscow. Although the *Comptes Rendus (Doklady) de l'Académie des Sciences de l'URSS* covers all the sciences, almost every issue contains work by physicists. The journal is published about once in ten days. Articles are seldom longer than three or four pages, and they deal in either English or French with the very latest results of work in progress or just completed. The editorial address is Kazan, rue Baumann, 19. To science students of the Russian language this journal is of special interest, as it is a direct translation of the Russian edition. Both editions are received by the Science Section of the S.C.R., 98 Gower Street, London, W.C.1. Although the *Bulletin de l'Académie des Sciences de l'URSS, Série Physique* is published in Russian, a short abstract in English of each paper is given in the earlier volumes. By 1943, this practice had stopped, presumably owing to war difficulties.

The most complete sets of journals are to be found in the national libraries of the Patent Office, the British Museum and the Science Museum, and in the private library of the Royal Society. The British Museum has a list, which can be seen in the Reading Room, of scientific and technical periodicals received from the U.S.S.R. during 1933-42. A similar ASLIB list is out of print, but can be seen at 31 Museum Street, London, W.C.1. Perhaps the fullest abstracting service from Russian journals is that of the *Chemical Abstracts* of the United States. The fullest card-index of the present whereabouts of any particular number of a journal is that of ASLIB. This card-index is of great value to the research worker as it covers all the main libraries of the country. At present, no one library has a complete run of any current Russian journal. An index of each separate number is therefore essential, and the ASLIB index is kept up to date in step with the information supplied by the separate libraries.

A note may be added on transliteration. At least four different systems are in use in the London libraries, and even the Academy of Sciences has not yet reached uniformity, for Prof. Kapitza's name is spelt

differently in two different journals. When the controversial symbols occur in the middle of a word no harm is done. A state of affairs in which an author's name may occur under *c* in one index and *t* in another is, however, very confusing. Research workers who do not read Russian would find it well worth the small effort needed to learn the Russian alphabet and system of transliteration for, in physics at least, many of the technical terms can be recognized as soon as they are transliterated even without the use of a dictionary. Mathematics, tables of results, graphs, diagrams and photographs can therefore be recognized from the captions, which usually involve little grammatical construction. A technical English-Russian dictionary is available (by A. E. Chernukhin, State Theo Tech Pub House, Moscow, 1934), but no Russian-English technical dictionary has been published. There is at present no technical Russian grammar. The writer wishes to thank the authorities named for help in collecting the above data, and would be grateful to receive additional information or corrections of errors for which he is alone responsible.

W. H. GEORGE

POST-WAR UNIVERSITY PROBLEMS IN THE UNITED STATES

THE report of the president of Harvard to the Board of Overseers is always an important document. On this occasion¹ it is perhaps more so than usual, because Dr J. B. Conant reviews the part that ought to be played by universities in the demobilization period, and he gives an account of the Harvard proposals. British universities have been facing similar problems, and no doubt much can be gained by a consideration of what universities in the United States are proposing to do. There will always, of course, be some differences that originate from differences of outlook and position.

During the past year, Harvard has evolved the general outline of its programme, and though designed for the period of large-scale demobilization, it is equally applicable to the earlier intervening period when the number of 'veterans' is not likely to be large. Two considerations directed the planning. The first was to provide several opportunities each year for returning soldiers to enter the university without having to wait for the commencement of the next academic year, and the second was to shorten the total time necessary to complete the educational rehabilitation. Both of these are worthy considerations, though they should be regarded as essentially post-war measures and not ones that would normally be desirable under peace-time conditions. In order to achieve these ends the College and the Graduate School of Arts and Sciences will have two terms of sixteen weeks and one of twelve, and a returning soldier will be able to enter at the beginning of any one term.

Dr Conant remarks that there is little or no enthusiasm for such a programme as a permanent basis, but he does express the opinion that it is an improvement on the old pre-war 32-34-week two-term academic year.

Harvard's present 48-week academic year has produced signs of strain in the student body, and no doubt similar strains have been evident in student bodies of British universities, especially during the past four years. It would appear that Dr Conant

considers that a 38-40 week academic year is about the most suitable, because instruction is not too long nor too intensive, and there is time for reading (especially since a reading period of two weeks prior to the examinations is probably included). This contrasts with the Oxford and Cambridge year of about 24 weeks, where instruction has perforce to be intensive and the student lives in a whirl from the moment he comes up to the time he goes down. In other universities in Britain the academic year is somewhat longer and the pressure is probably not so great. The length of the academic year would seem to be a problem that should have some reconsideration in the light of present-day conditions of living.

Turning to problems of admission, Dr Conant rightly issues a warning lest academic formalities and institutional rigidity drive away men with ambition and imagination. This is probably one of the greatest post-war problems facing the universities, and it will require all the tact and understanding of those who are called upon to deal with the ex-servicemen.

There are two other items in this report that merit attention. The first concerns the appointment to life positions on the various faculties. Naturally a university tries to secure the very best qualified men, but this is by no means easy as one may see from a study of the staff roll of any university. How far a proper solution has been found can be gauged by Dr Conant's comment, "that nine times out of ten the normal forces working within any special segment of the University make for a good appointment, but against an excellent appointment. And it was President Lowell who said, 'the surest way to ruin a University faculty is to fill it with good men'". This is an important truth which universities would do well to bear in mind, and it may be that new systems for making permanent appointments need to be evolved.

The second item, which should be heartily endorsed in Britain, is a suggestion that not too long after the War a comprehensive picture should be placed before the American public of the part played by the respective universities in the war effort, "For such a picture would go far towards fortifying the faith of the nation in its institutions of advanced learning". Britain has really only begun to appreciate the value of the universities during the War, and a justification of their immediate enlarged monetary demands could perhaps be better appreciated by the general public if some similar picture of their war effort were to be presented. Beautifully illustrated brochures have been produced showing what the Navy, Army and Air Force have achieved during certain phases of the War. Could not a statement be issued showing the work of the universities? Here, however, a word of warning is necessary, and one cannot do better than conclude with Dr Conant's own words "if the story is told piecemeal and the approach is in a spirit of aggrandizement of a particular University and the claiming of a large measure of credit for this or that discovery or participation in this or that military operation, the public will soon sicken of the tale, the less glorification of the activities of the home front the better. What is said must be couched in terms of humility if it is to harmonize with the spirit of sacrifice and valour of those who bore the burden of actual combat".

V. J. CHAPMAN

¹ Harvard College Report of the President, 1943-44

FORTHCOMING EVENTS

Monday, June 25

FARMERS' CLUB (at Kingsway Hall, Kingsway, London, W C 2), at 2 45 p m—Mr J Turner "International Co-operation in Agriculture"
 ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore, London, S W 7), at 3 0 p m—Annual General Meeting

Tuesday, June 26

ROYAL ANTHROPOLOGICAL INSTITUTE (at 21 Bedford Square, London, W C 1), at 2 p m—Annual General Meeting Prof J H Hutton "Problems of Reconstruction in the Assam Hills"
 QUEKETT MICROSCOPICAL CLUB (at the Royal Society, Burlington House, Piccadilly, London, W 1), at 7 30 p m—Mr F E J Ockenden "Polarized Light"

Wednesday, June 27

ASSOCIATION OF AUSTRIAN ENGINEERS, CHEMISTS AND SCIENTIFIC WORKERS (NORTHERN BRANCH) (at Austria House, 260 Oxford Road, Manchester), at 7 p m—Dr M Ruhemann "Low Temperature Physics"

Thursday, June 28

LONDON MATHEMATICAL SOCIETY (at the Royal Astronomical Society, Burlington House, London, W 1), at 3 p m—Mr A S Besicovitch, F R S "The Problem of the Area of a Surface"

Friday, June 29

PHYSICAL SOCIETY (at the Royal Institution, Albemarle Street, London W 1), at 5 p m—Prof Ragnar Granit "The Electrophysiological Analysis of the Fundamental Problem of Colour Reception" (Thomas Young Oration) Members of the Colour Group of the Society, and members of the Physiological Society are invited
 INSTITUTION OF CIVIL ENGINEERS (Great George Street, Westminster, London, S W 1), at 5 30 p m—M Demaret, president of the Société des Ingénieurs Civils de France, on the general activities of French engineers under the German occupation

Saturday, June 30

ASSOCIATION FOR SCIENTIFIC PHOTOGRAPHY (at the Alliance Hall, Westminster, London, S W 1), at 2 30 p m—Mr H White "Make the Photograph tell a Story"

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned

LECTURER IN PHYSIOLOGY to standard of Ph C and B Pharm, and a LECTURER IN GEOGRAPHY able to take work to the standard of the B A Honours and B Sc Special Examinations of London University—The Registrar, Portsmouth Municipal College, Portsmouth (June 27)

INSTRUCTOR (full-time) qualified to teach ELEMENTARY ENGINEERING, WORKSHOP PRACTICE, and the Care of Agricultural Machinery to members of Young Farmers' Clubs—The Chief Education Officer, County Offices, Chelmsford (June 30)

ASSISTANT LECTURER IN AGRICULTURAL ECONOMICS—The Registrar, University College of Wales, Aberystwyth (June 30)

ASSISTANT LECTURER IN PHYSICAL AND INORGANIC CHEMISTRY—The Acting Registrar, Queen Mary College, c/o King's College, Cambridge (June 30)

ASSISTANT LECTURER IN BOTANY—The Registrar, The University, Manchester, 13 (June 30)

SUPERVISOR AND MANAGER OF THE EXPERIMENTAL FARM, East Malling Research Station, near Maidstone, Kent—The Secretary (June 30)

INSPECTOR OF MACHINERY IN MINES AND FACTORIES, Government of Northern Rhodesia—Ministry of Labour and National Service, Central (T and S) Register, Room 5/17, Sardinia Street, London, W C 2, quoting C 2612 A (June 30)

AGRICULTURAL TRAINING OFFICER to the Cheshire War Agricultural Executive Committee—The Executive Officer, Reaseheath, Nantwich, Cheshire (June 30)

UNIVERSITY DEMONSTRATOR IN ENGINEERING—Dr R D Davies, Secretary of the Appointments Committee, Engineering Laboratory, Cambridge (July 2)

LECTURER IN GENERAL ENGINEERING SUBJECTS, and a LECTURER mainly for ENGINEERING MATHEMATICS at all stages—The Registrar, Merchant Venturers' Technical College, Bristol, 1 (July 4)

ASSISTANT ENGINEERS for the Iraqi State Railways—The Ministry of Labour and National Service, Appointments Department A 9, Room 5/17, Sardinia Street, Kingsway, London, W C 2, quoting C 2520 A (July 6)

LECTURERS (2) IN THE DEPARTMENT OF PHYSIOLOGY—The Secretary, The University, Aberdeen (July 7)

ENGINEER AND SURVEYOR to the Isle of Wight Rivers Catchment Board—The Clerk to the Board, County Hall, Newport, I O W (July 7)

HEAD OF THE DEPARTMENT OF PHYSICS AND DIRECTOR OF THE LABORATORIES in the College of Technology—The Director, College of Technology, Manchester 1 (July 9)

DIRECTOR OF SIGNALS AND RADAR DEVELOPMENT in a Government Department—The Ministry of Labour and National Service, Appointments Department, Room 5/17, Sardinia Street, Kingsway, London, W C 2, quoting D 1281 A (July 10)

SUPERINTENDENT POSTS (4) in a Government Research Establishment—Post 1 (Reference No C 2656 A) candidates should be well qualified in PHYSICS with a knowledge of Mechanical and Electrical

Engineering and a wide experience in research work, Post 2 (Reference No F 4376 A) candidates should be well qualified in the CHEMISTRY AND PHYSICS OF EXPLOSIVES and should have experience in handling and filling of explosive stores Post 3 (Reference No F 4377 A) candidates should have a wide knowledge of PHYSICS and PHYSICAL CHEMISTRY with considerable experience in research in one of these subjects, Post 4 (Reference No A 943 A) candidates should possess high academic qualifications in APPLIED MATHEMATICS, MATHEMATICAL PHYSICS and considerable experience of theoretic research—The Ministry of Labour and National Service, Appointments Department, Room 5/17, Sardinia Street, Kingsway, London W C 2, quoting the appropriate Reference No (July 10)

CHIEF ENGINEER in a Government Establishment dealing with the design of Armaments—The Ministry of Labour and National Service, Appointments Department, Room 5/17, Sardinia Street, Kingsway, London, W C 2, quoting C 2657 A (July 11)

Grade II(b) LECTURER IN MECHANICAL ENGINEERING—The Secretary, The University, Birmingham, 3 (July 31)

DIRECTOR OF THE INSTITUTE FOR RESEARCH IN AGRICULTURAL ECONOMICS, University of Oxford—The Registrar, University Registry Oxford (August 4)

SECRETARY TO THE INSTITUTION OF NAVAL ARCHITECTS—Council the Institution, 10 Upper Belgrave Street, London, S W 1 (August 3)

ASSISTANT IN THE DEPARTMENT OF CHEMISTRY, with special knowledge of Physical or Inorganic Chemistry—The Secretary, The University, Aberdeen (October 1)

TOBACCO EXPERT as head of the Agricultural Section of the Directorate General of Tobacco Monopoly of the Government of Iraq, improve varieties grown and study picking, drying and packing, able to carry out experimental work on the selection of seed and soil The Ministry of Labour and National Service, Appointments Department, Sardinia Street, London, W C 2, quoting O S 873

WARDEN AND ASSISTANT LECTURER IN AGRICULTURE at the Ké Farm Institute, Sittingbourne, Kent—The Principal

CIVIL, MECHANICAL AND ELECTRICAL ENGINEERS in the Colonial Engineering Service—The Director of Recruitment (Colonial Service) 15 Victoria Street, London, S W 1, or the Ministry of Labour and National Service, Room 5/17, Sardinia Street, London, W C 2, Appointments Dept A 9

GENERAL AGRICULTURAL OFFICERS and also SPECIALISTS IN PLANT PATHOLOGY, GENETICS, etc, for service overseas in the Colonial Agricultural Service—Director of Recruitment (Colonial Service), Victoria Street, London, S W 1, or Ministry of Labour and National Service, Room 5/17, Sardinia Street, London, W C 2, Appointments Dept A 9

A PROFESSOR OF CIVIL ENGINEERING, and a PROFESSOR OF MECHANICAL ENGINEERING at Canterbury University College, Christchurch, New Zealand—The Secretary, Universities Bureau of the British Empire, c/o University College, Gower Street, London, W C 1

TEACHER OF MECHANICAL ENGINEERING SUBJECTS, and a TEACHER OF ELECTRICAL ENGINEERING SUBJECTS qualified to teach both A and D C to National Certificate standard—The Principal, Technic College, Talbot Road, Stretford, Lancs

GRADUATE TEACHER FOR CHEMISTRY, and a GRADUATE TEACHER FOR MECHANICAL ENGINEERING SUBJECTS—The Principal, Cumberland and Technical College, Workington

PHYSICIST to the Stoke-on-Trent Regional Radium Centre—The House Governor, North Staffordshire Royal Infirmary, Stoke-on-Trent

GRADUATE MISTRESS FOR BIOLOGY—The Principal, County Secondary School, Workington, Cumberland

LECTURER IN GEOGRAPHY, and a LECTURER IN SOCIOLOGY, at the Portsmouth Training College—The Registrar, Municipal College Portsmouth

ASSISTANT MASTER IN THE JUNIOR TECHNICAL SCHOOL, qualified to teach Science and Mathematics—The Principal, Royal Technic College, Salford

SOCIAL SCIENCES AND THE CIVIL SERVICE

THE future position of the Civil Service in Great Britain turns on two fundamental factors: first, the adequacy of the methods at present in use in the Civil Service for handling the new and wider range of problems with which it is called upon to deal in the discharge of a new and more positive conception of government, and what changes, if any, are required to enable it the better to discharge those functions; secondly, the capacity of its personnel to handle those problems constructively, imaginatively and efficiently, with its corollary, the consideration of methods of the recruitment, training and tradition of the Service. It is not, of course, possible to separate questions of methods and men in practice quite so sharply. The personnel of a Civil Service may be defective because of lack of inherent capacity, but the presence of competent or incompetent officers in the Service and their subsequent attainments are determined largely by the methods of recruitment and training employed, just as the tradition of the Service has a large influence on its attractiveness as a career for the ablest minds and finest characters in the community it serves. Equally, it is true that no perfection of administrative methods and machinery will ensure efficient functioning unless the Service attracts administrative ability as well as integrity.

No serious criticism of the Civil Service, however, can ignore the fact that the extension of Government activities has come to stay, the social service State, the implementation of a policy of full employment, calling for a more positive conception of government, will impose fresh demands on the whole machinery of government as well as on the men to whom the actual work of government is entrusted. Leaving on one side the question of machinery, we have to ask ourselves, first, whether we are getting into the service of the State a sufficiently representative sample of the highest ability available, and then, having recruited from all possible quarters the right material, whether we are making the most effective use of that material.

These are the questions with which in the main Dr. E N Gladden is concerned in his recent book*, but his contribution is disappointingly small. He recognizes that the War marks a great change in the social structure of our world and that to-morrow's needs will require a new Civil Service for their fulfilment. But while he asks the question whether our present administrative machine is flexible enough to meet these new needs, and contributes an admirably lucid account of the evolution of the national administration and of recent criticism of the Civil Service as well as of its development in Great Britain, his analysis scarcely seems to go deep enough. He says the right things about official integrity and detachment, the method of open competition, and the like without being platitudinous. His review of recruitment is eminently sound, with its pertinent reminder that while the interviewing methods adopted

by the Civil Service Commission have been found satisfactory, it is doubtful whether the conditions of a short interview can have permitted a really high degree of objective accuracy to be attained.

Similarly, Dr Gladden's review of training rightly emphasizes that normal methods of open competition pre-suppose a complete system of post-entry training, but while he admits that such training, especially that by encouragement, is largely absent, he gives little if any indication as to how this should be remedied. For a successful system, he points out, two changes would be essential: first, a new attitude by those in control, and, secondly, a Civil Service which would permit the advancement of the talented man more effectively than the present system. He criticizes the introduction of the training grade of the executive class as having too long a salary-scale and numbers too high in proportion to the higher grades of the class, and his discussion of promotion questions is likewise critical rather than constructive. It exposes the weaknesses in the assumptions upon which the use of a seniority list as the only basis of promotion rests, without indicating the measures which might be taken to increase the validity of those assumptions. Again, he points out that the qualities required for promotion, at least to supervisory posts, are not easily subjected to the examination process, and he recognizes the importance in a democracy of tapping the largest possible recruitment area.

Dr Gladden's own proposals, to which the second part of the book is devoted, are designed to overcome some of these difficulties. The Civil Service organization must fulfil four requirements: it must be capable of meeting the functional aims for which it has been created; it must be synchronized at the recruitment stage with the school-leaving ages as prescribed by the different strata of the educational system; it must be able to meet the long-term changes postulated both by the alterations in the social environment and by the general development of administrative technique; and it must, while conforming to a centralized plan, be capable of meeting the various special demands of the separate departmental units. Briefly, Dr Gladden proposes to secure this by constituting a new general clerical class to cover the present clerical-executive-departmental field, and by recruiting up to 50 per cent of the administrative class within the Service. The general clerical class would be divided into ten seniority or salary groups common to the whole Service, and for promotion purposes, group seniority would replace individual seniority. Recruitment from outside would be to the lowest three groups, the examination being cast on the present lines to obtain candidates from the primary plus stage, from the intermediate secondary stage and from the higher secondary stage. The scheme would provide for demotion, where necessary, for effective probation, and for transfers between Ministries to be arranged by a personnel organization board which would also control the staffing of new Ministries. A central training committee would be established and the study of public administration encouraged.

Without entering too deeply into the details of Dr Gladden's proposals, and whether they are likely to secure all that he desires, it is clear that he recognizes the extent to which the chief problems of personnel organization reside in the management of the administrative rank and file, in the application of general rules to staff and in the selection therefrom of individuals for special tasks and positions. While his scheme may well ensure that the principles of objectivity in staff selection, both in recruitment and promotion, continue to be rigorously applied, it may be questioned whether they offer any real contribution towards the increase of flexibility of the Service where questions arise of taking into the sphere of government new institutions hitherto outside the State's orbit. Despite the wide range of his final chapter with its clear recognition of the new and wider functions of government, of the necessity for new social incentives, the importance of individual efficiency and of the place both of expert and administrator in government—the only expert, he says pertinently who bids fair to rule is the propagandist, without whose aid no dictator could rise to power, no government maintain its position, and no new programme gain the adherence of the crowd—Dr Gladden is somewhat superficial. His conclusion that quite a modest measure of reform should suffice to fit the Civil Service to the superhuman tasks with which the nation's administration will be faced in the period of reconstruction is not altogether convincing.

Indeed, Dr Gladden's book can be contrasted with a modest little study by Elizabeth Macadam*. Her brief review of the provision of training for the social services, to which Mr S. W. Harris contributes a foreword, well illustrates the limitations of Dr Gladden's book, although Miss Macadam is addressing herself specifically to a more limited problem, the importance of which was specially emphasized by Sir William Beveridge in his report on social insurance and allied services. The success of a social security policy will ultimately depend largely on efficient administration, and such administration in its turn depends not only on the efficiency of rank and file workers responsible for active work and personal contacts, but also on the quality of the numerically much smaller administrative staff responsible for direction and policy.

This aspect of the Civil Service has already attracted attention. It was ably discussed, for example, by Mrs Joan S. Clarke in a chapter "The Staff Problem", contributed to the volume of essays entitled "Social Security" edited by Dr W. A. Robson, and Mrs Gertrude Williams has some pertinent observations in the final chapter of her study "The Price of Social Security". Mrs Williams emphasizes the necessity of quantitative thinking by the administrator to supplement the principles of the use of powers conferred by law. For this, the Civil servant requires more knowledge of the workaday world, and the content of his mind as well as its quality is important. More and more it is required of the Civil Service administrator that he should be

* *The Social Servant in the Making*. By Elizabeth Macadam. P. 146 (London: George Allen and Unwin, Ltd., 1945) 6s.

not only more competent to deal with situations as they arise, but also that he should know how to create the situation by looking ahead and preparing for it. Well may Miss Macadam observe, of objections to proposals to recruit older men and women to the administrative class, that something must be wrong with the machine of government if a few years work outside Whitehall makes a man too old at thirty to acquire a knowledge of its technique.

Miss Macadam, recognizing that social services have no hard and fast boundaries, strongly supports the plea originally advanced by Sir Ernest Barker that the higher administrative posts of the Civil services should be opened to a maturer type of candidate than those who successfully pass a competitive examination at an early age. This, in her opinion, is an essential step towards a modernized and socialized Civil Service, and the Government's proposals already announced in the White Paper on recruitment during the reconstruction period are a move in this direction. Next, she considers the university as the appropriate centre for training, and holds that every university should have its school of social study, though not necessarily the same equipment or identical aims. Schools in great cities, for example, will tend to become centres of instruction and research on a large scale. Oxford has opportunities for the study of rural conditions from its centre at Barnett House, while Manchester, Glasgow and Leeds should become centres for training in industrial personnel and welfare.

All this, of course, would implement the provision and admission of economists, sociologists, psychologists and statisticians, which has been emphasized by Mrs Joan Clarke as so important now that constructive long-term thinking and exercise of the newer mental disciplines have become a government function of the first importance. Again, if organized courses for junior Civil servants on the lines of the staff college idea are established, Miss Macadam suggests that they would be better held at universities than concentrated at a special institution. The modern university is not so segregated that courses of study for public service on the lines laid down in the British Association Committee's report would fail to attract many different types of candidates or to offer opportunities for very varied contacts.

Some of these suggestions of Miss Macadam clearly deserve closer consideration in planning the post-war development of the universities of Britain. The establishment by the universities of sub-centres of social study in areas out of reach of a university is more a matter for inter-university discussion than for independent action, as is also the specialized development of social study schools, while her reference to the need for a National Institute of Social Studies comparable with the Royal Institute of International Affairs points to a further problem in which co-operative planning will be required to avoid overlapping in research.

But there is a further reason for more deliberate planning and co-operation in this field. Unless the special fields of the social study schools of the universities are planned in co-operation in some such

way, there is danger that the individual schools will not receive a sufficient regular supply of students. Moreover, as Miss Macadam again points out, while the content of mind is important, quality is important also, and we shall not attract the best type of entrant unless we open up wider possibilities of promotion in the Civil Services for those who qualify in this way. More sources of financial help during training are also needed, but above all it is imperative to remove the deterrent of the relatively low salaries and limited opportunities of promotion at present available to those who enter the statutory social services. Nor should it be forgotten, as Miss Macadam reminds us, that this applies to the local government service also, where a socially trained administrative staff is equally important. Trained practitioners in the social sciences or in any other field of science may be ineffective if those under whom they serve have no conception of what social or scientific work means. There could be no more convincing demonstration of this than the difficulties which the proposals of the White Paper for a National Health Service have encountered through the well-founded distrust of the medical profession of local government administration. Had a sufficiency of administrators of the right outlook and training made their influence felt throughout that service, the whole reaction of the medical profession to the Government's scheme might have been fundamentally different.

Of the two books referred to above, Miss Macadam's appears to deal with the more fundamental issues in spite of its professedly narrower scope. She is more suggestive and her observations on the contribution of the university are a real contribution to the discussion of the place of the university in the modern world. Recognizing the grave danger of isolation in the teaching of particular aspects of social problems, especially those dealing with abnormalities and liable to fall completely out of focus when treated separately, she urges that university control provides a guarantee against the equally real danger of political or other forms of propaganda. The fact that social politics border so nearly on party politics is a strong reason why candidates for training should come under the influence of men and women who can be expected to preserve as impartial an attitude as possible. Both books draw freely on current reports and criticism of the Civil Service, though Miss Macadam's book might have been better documented, and Dr Gladden's select bibliography unfortunately omits reference to the British Science Guild's report. While they make little fresh contribution to the discussion, they nevertheless disclose the fundamental principles which must be followed in moulding the Civil Service in Britain to meet the needs of the future. The type of personnel required is already becoming clear. The traditional integrity of the Service must be maintained, and its members, from the highest grade to the lowest, must approach their tasks in the knowledge that they are indeed servants of the community. In addition, they must be imbued with a spirit of endeavour, and able to recognize the needs of the swiftly changing character of the world in which we live.

DISTRIBUTION PATTERNS

Maps for the National Plan

A Background to the Barlow Report, the Scott Report, the Beveridge Report. Prepared by the Association for Planning and Regional Reconstruction. Pp. iv+120 (London: Lund, Humphries and Co., Ltd., 1945) 15s

THE title, "Maps for the National Plan", may perhaps mislead purchasers of the work under review, for its anonymous compilers are members of a fact-finding group, and the maps in question do not present a plan, but have been chosen simply as furnishing in visual form a large collection of data deemed to be relevant to planning. In order to drive home their relevance, each map is faced by a column of verbatim extracts from the Barlow, Scott or Beveridge Reports, and these are usually well chosen, although the relation of catchment board boundaries to defective rural water supply seems a trifle tenuous.

The area covered is that of England, Wales and Scotland (excluding the Orkney and Shetland Islands), and all but one or two maps are gridded in accordance with the system adopted by the Ordnance Survey. On the key map entitled "Chief Urban Areas" the grid is ruled at 10-kilometre intervals, and this map is duplicated on a stout transparency, so that it can be laid over any other map in the series. It will prove rather a handicap to users that none of the counties, and very few of the towns, are named, which means that the maps must be used with an atlas. A second transparency, showing the "Distribution of Population" according to the Registrar-General's estimates for 1938, also loses much of its usefulness owing to the very unintelligent use made of the so-called 'dot method' of statistical mapping, one that has limitations which by now should be sufficiently well known. On a large number of the maps, however, the cartographical devices employed are undoubtedly fresh and effective, and the whole style of printing and production is at a very high level, especially by war-time standards. The method of binding, which certainly has the advantage that the maps lie perfectly flat, as well as the finished appearance of the maps themselves, is a reminder that a close scrutiny of a 'planner' usually reveals, not a lover of books or learning, but an architect or an engineer. Tribute has, however, been paid to the scholar's methods, for in an appendix the sources drawn upon for each map are carefully listed, and where necessary supplementary statistics and diagrams are supplied.

The analysis and interpretation of the maps is, however, left entirely to the reader, and this he may find difficult unless he is already accustomed to map techniques. Why, he will ask, could not the same information have been presented in literary form? The short answer to his question is this: Maps can reveal, as neither words nor figures can, whether or not a particular distribution shows 'pattern'. If the distribution, say of unemployment, is uniform or haphazard, it will show no pattern, if it is influenced either directly or indirectly by geographical location, it will. Maps such as these do away with the idea that industry, save for mining and shipbuilding, can 'go anywhere', and map techniques are now being employed in various Ministries to investigate this extremely complex problem of location. The basic pattern of any country is determined by its geological

structure, which shows itself most clearly in the disposition of surface relief and drainage, soils and mineral resources. Surface relief and drainage in their turn underlie accessibility, while population aggregates, from villages up to conurbations, are usually found to be rooted in some combination of accessibility and resources, the latter including water supply and soil quality. Sir Halford Mackinder long ago pointed out the fundamental contrasts between the geologically older west and north-west of Britain and the geologically younger east and south-east. The network of traffic links between the two, at its densest in the axial belt running from the metropolitan area to the Mersey, provides a zone of superior accessibility, the importance of which can be traced now clearly, now dimly, through many of these maps. There is little doubt that the inaccessible location of the uneconomic location so far as industry is concerned, and also the undesirable location so far as the majority of gregarious mortals see it.

There is small warrant, therefore (security from attack apart), for the widespread ruralization of industry which many planners desire to see. A map, entitled "Country Towns Selected for Development" the only didactic one in this collection, should be examined in conjunction with the maps showing amenities and services, including, for example, the electric grid, medical men and secondary schools. The authority for this map is Mr A. E. Smailes, whose published work (cited in relation to several other maps) is scarcely deep or searching enough to make him altogether a safe guide to follow.

It would be easy to find fault with these maps in detail: the economist would query this, the statistician that, the geographer something else. But looked at as a whole, the book is stimulating, and challenging. Here are matters which must be considered, which will be neglected at our peril. Who, for example, will be able to pass over lightly the pair of maps showing the proportion of the young to the old in 1911 and 1931 respectively? True that, by a perverse blindness to the importance of cartographical conventions, the areas proportionally richest in children in 1911 are shaded in deepest black, but in 1931 there are no such 'black spots'.

E. G. R. TAYLOR.

FOURIER AND TAYLOR SERIES

Lectures on the Theory of Functions

By Prof J. E. Littlewood. Pp. viii+243 (London: Oxford University Press, 1944) 17s 6d. net.

THE material of these lectures is drawn from the most central and fundamental of recent developments in the general theory of functions of real and of complex variables. The introduction and Chapter are already well known to the author's students, and will now be especially welcomed by a wider circle.

The introduction is mainly devoted to functions of a real variable and includes sections on inequalities, the analysis of function classes in relation to integration and generalized convergence, Fourier series, and harmonic functions of two variables, and gives in relatively few pages a remarkable amount of these extensive subjects. There is also a special study of some curious power series. Chapter I deals with the foundations of the maximum modulus principle and the convergence properties of sequences of analytic

functions, but is mainly concerned with the theory of conformal representation of simply and multiply connected domains in a plane including the correspondence of the frontiers. Many accounts containing more or less the same subject-matter have been published; but the present one is notable for the great care which has been taken with the proofs and explanations of the subtle and difficult features with which the subject abounds.

The first volume ends with Chapter 2, which has been rewritten and extended with the collaboration of Dr Rogosinski. This commences with a brief but substantial account of the theory of subharmonic functions, and for the rest is concerned with a special group of comparatively recent discoveries based on the notion of 'subordination'. In elementary calculus we are accustomed to argue from geometrical properties of the curve representing a function to properties of its derivatives or integrals and vice versa. The analogous process for differentiable functions of a complex variable is more elaborate because of the four-dimensional nature of the geometrical representation, and because the values of the function and its first derivative even at a single point influence their behaviour throughout their whole region of existence. This property (exhibiting power series and Fourier series in sharp contrast) is illustrated by a discussion of some of the simpler results related to Bloch's theorem. If, on the other hand, the values taken by the function are in any way limited, then its rate of growth at maximum, in the average, and in terms of its differential coefficients is correspondingly restricted. This consideration is developed in the "Lectures" for functions the values of which omit certain regions, curves, or isolated points, including in particular the author's own theorems on functions omitting a sequence of points and the proof of the Bieberbach conjecture in special cases.

The book possesses two very unusual features which overshadow the mere contents in importance and distinguish it from the more common compendium of (sometimes inadequate) quotations. One is the extreme care which has been taken over every detail of logic and presentation, and the other is the remarkable artistry with which so many different aspects are arranged in a logical and readable sequence. It is therefore unfortunate that bibliographical references of the customary standards have not been added on publication of the "Lectures".

A. J. MACINTYRE

MODERN METEOROLOGY

Descriptive Meteorology

by Prof Hurd C Willett Pp viii+310 (New York: Academic Press, Inc., 1944) 4 dollars

WEATHER is still one of the major factors in war, air warfare especially has resulted in the intensive teaching of meteorology on an unprecedented scale. Teaching requires books, and the last few years have brought a number of excellent textbooks, mostly from the United States, where lavishness in printing is still possible. The latest example, by Prof H C Willett, maintains the high standard, is excellently printed on good paper, well illustrated, and, more important, it is lucid, readable and completely modern. The arrangement follows the usual

lines for a text-book of physical and dynamical meteorology (the title "descriptive" is over-modest), it begins with definitions, the composition of the atmosphere and the effects of vertical movements under adiabatic conditions. Chapter 3 deals with the heat balance of the atmosphere and includes a revision of the classic diagram due to W H Dines, which embodies the most recent data but is not quite so clear as its prototype. There are two striking vertical cross sections of the atmosphere over North America from 72° to 18° N, based entirely on *radio-sondes*.

The next two chapters, on evaporation and condensation, and wind velocity, are on accustomed lines and do not call for comment, but the treatment of the general circulation in Chapter 6 is of great interest. The vertical cross-sections of temperature and pressure are used to reconstruct the zonal geostrophic winds above North America, but these diagrams are not clearly explained, moreover, they could profitably be supplemented by sections showing the variations of the observed winds with height. Charts of observed normal winds at 10,000 feet are given in a later chapter, but these afford only a very limited comparison. From these sections the author comes to the unorthodox conclusion that the variation of height of tropopause with latitude results from the dynamics of the general circulation and not from the strong heating of the tropics.

"Secondary circulations" include the rather odd grouping of monsoons and hurricanes. The account of the Asiatic monsoons is perhaps over-simplified, for example, the author implies that there are no rain-producing agencies in central China in winter, omitting mention of the storms associated with the passage of shallow continental depressions. The account of the development of a hurricane is excellent, especially the analysis of the conditions within the 'eye' of the storm.

The chapter on air-mass characteristics contains a good deal of new matter, including sub-categories for stable and unstable air based on thermal stratification at high levels, which make a useful extension of the earlier classifications. It is now recognized that "air masses which come from the same source region at the same season and by the same trajectory may differ greatly in their upper level stratification". The world charts of air-mass source regions are of great interest, but need to be studied in relation to maps of the prevailing winds. Unfortunately such maps do not appear anywhere in the book—a notable omission which ought to be remedied. Extra-tropical depressions, both surface and upper air, come under the heading of "secondary circulations of dynamic type", and along with much that is familiar, include a good deal of recent analysis of upper air conditions. "Tertiary circulations" embrace a miscellany of phenomena, from land and sea breezes to tornadoes, there is a new theory of the Föhn as primarily a change of air-mass rather than a result of dynamical warming. The book ends with a chapter on synoptic representation and a sketchy section on forecasting.

From this brief account it is evident that Prof Willett has achieved something of a feat, at a time when meteorology is developing rapidly he has almost completely eliminated the usual lag between the publication of research in the scientific journals and its appearance in text-books. No doubt this is largely due to his own activities in one of the storm-centres of research.

C E P BROOKS.

A Background of Physical Geography

By George P. Kellaway Pp viii+232 (London Macmillan and Co., Ltd., 1945) 8s 6d

THERE is need for more attention being given to the physical basis of geography in school work, too great attention to the human side, with neglect of the background, may encourage a subjective approach. This short volume is an attempt to supply the physical background for higher school and intermediate university geography.

The book covers a wide field with different degrees of emphasis. Broadly speaking, half of it deals with land features and the oceans, and half with the atmosphere. After the usual introductory matter on the earth as a planet, there follow a few notes, rather too brief, on theories regarding the earth's origin and kindred matters; Wegener's theory and isostasy, each in one page, are compression carried to excess. Of the chapters on land forms and land sculpture, the least satisfactory is that on islands, where some revision is required in the sections on volcanic islands and coral islands. Darwin's theory of reef growth is not the only one. The chapter on the oceans is short and comprehensive, but the author should note that icebergs are never formed from sea-water. The term is not used for sea-ice. Since the temperature and salinity of ocean water are discussed, it would be well to consider the bottom water and its origin.

The final chapters, on climate, are the best part of the book, though it is not clear to the reviewer why a discussion of climatic regions should be headed "Natural Regions of the Earth." Reliable information concerning the true polar regions is not so scanty as the author suggests, and is quite adequate for a clearer view of polar climates, both north and south, than is given here. It is high time that the old well-worn and misleading diagram of the planetary winds, as they would be on an ideal water-covered globe, was abandoned. The notes on vegetation, given for each major climate, should, for students of geography, be more explanatory and not merely descriptive.

The book is well illustrated, and on the whole may serve the purpose for which it is intended.

Introduction to Quantum Mechanics

By D. E. Blochintsev (In Russian) Pp 484+79 plates (Moscow and Leningrad Unified State Publishing Co., 1944) 18 roubles

THIS modestly named volume is in fact a comprehensive treatise covering the whole subject of quantum mechanics. It summarizes the relevant basic discoveries of Planck, Compton, Einstein and Bohr in convenient mathematical form.

The chief sections are: basic principles of quantum theory, wave mechanics, relations between quantum mechanics, classical mechanics and optics, theory of movement of particles in a field of force, movement of charged particles in an electric field, theory of continuous spectra, radiation, absorption and dispersion of light by atomic systems, secondary quanta and quantum statistics, magnetic phenomena.

A series of appendixes summarizes and clarifies the mathematical framework of the treatise. There is an adequate subject index. Bibliographical notes are interspersed as footnotes.

In spite of the poor-quality war-time paper, the volume is a dignified one. The printing of extremely complicated mathematical functions has been well done.

Five-Figure Logarithm Tables

Containing Logarithms of Numbers and Logarithm of Trigonometrical Functions with Argument in Degrees and Decimals Pp iii+188 (London H.M. Stationery Office, 1944) 7s 6d net

THIS collection of five-figure tables has been compiled, as a war-time measure, to meet the ever-increasing demand, both in industry and elsewhere, for accurate numerical information of this kind.

The book is divided into three distinct parts. The first of these (occupying seventy-three pages) is a reproduction, from stereotype plates, of Chappell's table of logarithms, which gives five-figure logarithm of the numbers 10,000 to 40,000 and then those of 4,000 to 10,000 in that order. The second section is a photolithographic copy of von Rohr's table of five-figure logarithms of sines and tangents of small angles, over the range from 0° to 5°, for intervals of one thousandth of a degree in each case. Lastly there is a similar reproduction of Bremiker's table of five-figure logarithms of sines, tangents, cotangent and cosines of angles from 0° to 45°, for intervals of one hundredth of a degree in all cases. A table of constants is also appended.

Having regard to the urgent necessity for conserving paper supplies, it was considered unnecessary to provide a continuous pagination and the pagination of the three component tables has therefore been preserved unchanged. The original prefaces and explanations have also been omitted, and no instructions for the use of any of the tables have been supplied. The von Rohr and Bremiker tables have been reproduced with the authority of, and under licence from, the Custodian of Enemy Property.

It is worthy of note that the standard of reproduction and printing is very high.

J. H. PEARCE

Gardener's Earth

An Introduction to the Study of Soils for the Every-day Gardener By Dr Stanley B. Whitehead Pp viii+231+24 plates (London J. M. Dent and Sons, Ltd., 1945) 7s 6d net

THIS is an interesting production, one of the better class of books on gardening written for the non-technical reader. Although it is mainly about soil, it covers a wider ground, including manures and fertilizers, pests and diseases and crops. In conformity with the title of the book, the discussion of these subjects is based on their soil aspects, this form of treatment has led to some repetition, both between and within chapters, that calls for pruning when a new edition is prepared.

In his discussions of soil moisture and cultivation the author has fairly presented the results of modern research and technological investigations, in consequence, the alluring but inadequate picture of the soil pore-space as a bundle of capillary tubes finds no place in his exposition. The discussion of organic manures and artificial fertilizers is less happy. The non-technical reader may well wonder why the full (and excellent) account of artificials and their use is included, in view of the blunt statements about them in the chapters on the virtues of organics, and it is a little unfortunate that the objective and scientific treatment maintained over the greater part of the book is occasionally obscured in these chapters. With these reservations the book can be given a welcome. A special word of praise is due for the excellent illustrations.

B. A. K.

PLANT PATHOLOGY: TEACHING AND RESEARCH*

By PROF W. BROWN, F.R.S.

WE are now, we hope, approaching the realization of peace and of that kind of atmosphere in which biological work, and more especially research, can hope to flourish once more. We have every reason for believing that the next few years will see many changes—changes in our educational system at all levels, with resultant effects upon students who take up an applied biological profession, and changes in our agriculture which will lead to a different emphasis upon instruction and research in biological subjects. With these changes impending, it may therefore be opportune at this time to look back over the years of one's experience, and see how far the old system appeared to be satisfactory and where on the other hand it did not give the results which might have been expected.

As the scope of plant pathology varies somewhat from place to place, it will be well, first of all, to say a few words on this topic. My own experience has been substantially in the region of mycological plant pathology, that is, I am a plant pathologist in the narrower sense which is current in Great Britain, as for example in the calendars of universities and agricultural colleges. This narrower definition leads to difficulties in practice, as for example in delimiting the respective spheres of the plant pathologist and the agricultural entomologist in the study of insect-borne diseases. It is much better, I think, to use the words 'plant pathology' in a wider sense, and to mean by it the study of the plant in disease, whatever the cause may happen to be.

On this topic of definition, I would venture to go even further towards generality. The word 'disease' as it comes to acquire rather a special meaning, and to most people implies more than mere 'unsatisfactoriness'. I would be prepared to stake a claim as follows. Wherever a plant (or a plant product) is unsatisfactory for any reason whatever and in any respect whatever, as for example when the yield has been smaller in quantity or less desirable in quality than might reasonably have been expected, there one sees a problem for the plant pathologist. No doubt it would be very easy to state problems which fall within this widest scope and which would sound seriously if labelled 'plant pathological'. Such matters appeal to me as details, and the important point is to recognize the unity of aim, which is to achieve more and more control over the plant in certain desired directions. The technicians employed must of necessity be various—entomologists, geneticists, mycologists, soil chemists and others—but they are all harnessed to the one major purpose, the production of more and better plants. I need scarcely add that this is the main interest of the public, who apply in the long run the funds which render our work possible.

I have put in my title the phrase "Teaching and Research". The two are not easily separable, for there is general agreement that teaching will not long survive if the research side is dead. The necessity of research in a teaching institution, quite apart from the desirability of keeping the name of the place

upon the map, is all the more compelling if it is agreed that the object of teaching is not so much to inculcate a mass of facts which may soon be forgotten, as to instil methods of handling facts, and where possible of discovering new ones.

It would take too long to go into any detail as to what I think is the most desirable pre-graduation training for a man who intends to take up plant pathology as a career. The old system, or rather lack of system, under which we have been brought into the subject, can at least claim that it functioned in the best tradition of natural selection. But clearly one must set some limits to this sort of thing in the interests of efficiency and the saving of time. I would like to make some general observations under this heading.

First of all, what type of man, from the secondary schools, should we welcome as entrants into the biological field? Here I am giving my personal opinion, though I know that many of my colleagues are in agreement with me on this point. We must look here at the kind of training given in the schools.

There was a time, not so long ago, when botany was the only biological subject which found a place in the school curriculum. This applied only to a proportion of schools, and in these it was not on a level with the physical sciences. It was in general a subject for girls and for the weaker of the boys. In the ten years or so before the War there was a considerable change-over from botany to the composite subject biology. This movement was progressive and extended to schools which had not hitherto offered instruction in any biological subject. The expectation is that this development will continue after the War, so that we can look to a not-distant date when biology will take its place as a standard subject in schools, much on a level with physics or chemistry. Considered from the point of view of equipping the ordinary citizen for his life's work, this change has a great deal to recommend it, and I have not met anyone who seriously contests its merits. We are concerned here with the more limited question as to how it affects the equipment of students who go up to the universities bent upon a career in biology.

Frankly, I would say that we would rather that entrants into university biological departments did not have this preliminary biological training at school, and that for two reasons. One of these is probably temporary, the other, I fear, is permanent. As regards the first, we are still in the transition period, which may last for some time. For reasons which are sufficiently obvious, the standard of instruction at present reached varies very greatly from school to school, so that in the mixed batches who go up to the universities it is difficult to know where best we should begin. It is particularly with regard to laboratory instruction that we find the greatest unevenness, and obviously that is very important. No doubt this difficulty will lessen as times goes on. The second objection, of a more lasting nature, is this. Biological instruction in the schools has been developed at the expense of the physical sciences, and there is a grave risk that the biological student of the future will go up with an inferior grounding in these fundamental subjects. Once he has started on his biological work, he may never have the opportunity or the will-power to go back and make good the omission, and so the field of his usefulness may be permanently narrowed. Speaking broadly, one can say that there are some subjects of a kind that if one neglects them in one's

youth, one does not easily pick them up later. Physics, and more especially mathematics, are such subjects.

Summarizing what I have just said, I would picture the desirable type of student somewhat as follows. It is immaterial whether he has had any biological instruction or not, but he should be well founded in the basal sciences, and also have a natural interest in plants or animals. *A priori*, I would rather that he were a countryman who preferred the country to the town, as he would be more likely to feel at home there and to have a broad country background.

The choice of training centre for such a student lies between the biological departments of a university, which nearly always is situated in a large town, and an agricultural college, which is usually in the country. Both have their merits and limitations.

Students at an agricultural college have the advantage that they are not brought up in a theoretical or academic atmosphere, they are in country surroundings and are in contact to some extent with the practical side of things. At the same time I am not prepared to allow that a few years' or even a lifetime's residence at an agricultural college necessarily imparts the true inwardness of the farming life. Many farmers draw a sharp distinction between what is done at an agricultural college and what they consider to be practicable on the average farm. From the technical point of view the great objection to the ordinary agricultural college as a place for the training of specialists in the plant industry is the meagreness of instruction in the basal sciences. A sound and comprehensive course in the biological sciences seems to me to be essential, and that is what the agricultural colleges are not at present in a position to give. Of course, one must allow for exceptional cases, and I know personally some excellent research workers who have graduated by this channel. Nevertheless I consider them to be exceptional cases.

The strength of the university department is the weakness of the agricultural college, and vice versa. I need not dilate upon the social advantages which accompany the university life, but shall confine myself to the technical. It is of the greatest value to a student, in his undergraduate years and perhaps more so during a period of postgraduate research, to be able to rub shoulders with workers in other scientific subjects or in university subjects generally, with consequent broadening of his outlook. There are also the special advantages of access to advanced courses on topics related to his main study, for example, courses on physical chemistry, spectroscopy, and so on. These advantages are obvious, the disadvantages require fuller treatment.

The question has been seriously asked. Is the rarefied atmosphere of a university biological department a suitable training ground for a man who is going to specialize in problems of plant culture? Prof. W. B. Brierley, in his presidential address of some ten years ago to the Association of Applied Biologists, discussed this point in a very lively manner and had much to say about the academic man sickled over with the academic cast of thought. With much of what he said I find that I am in hearty agreement, though I am optimistic enough to believe that there has been an improvement in the interval. I do not think that you will find so many of the academic 'die-hards' flourishing in university circles as you would have found twenty years ago. It is also true that courses in botany and zoology are brought into line with current interests and activities,

by the introduction of new and the scrapping of old material, though it may well be that the process of modernization is not going on fast enough.

Speaking in particular of botanical courses, should say that the greatest weakness is the lack of intimate contact with growing plants. By intimate contact I do not mean merely looking at living plants. I mean actually handling them and growing them. It does not follow from this that I would like to train botanical students as gardeners or farmers, but I do hold that a training which deals largely with preserved plants and which is centred in a laboratory is lop-sided. Every effort should be made to bring the young student, from the earliest stage of his career, into contact with the practical growing of plants. This is desirable for all botanical students but more especially for those who intend to take up an applied side such as plant pathology. Practical contacts can be developed by arranging for students to work at research institutes or on farms during vacation periods, and it is clearly desirable that the facilities in university departments for experimentation in the field or glasshouse should be extended. Granted that such facilities are forthcoming, I feel sure that the proper place for the pregraduate training of the plant specialist, including the plant pathologist, will continue to be the university biological department.

The field of research in plant pathology which is appropriate for a university staff (as contrasted with that of a research institute) is no doubt fairly wide, but there are some obvious limitations, even when the facilities of laboratory and experimental ground are all that could be desired. The subject chosen should be one which could be expected to yield a result within a period of about two years, even though the primary object is not to obtain publishable results as such but to give training in research methods. Two years is a short time for outdoor research, where the kind of work possible is often dictated by the season, and especially when, as often happens, the first season must be largely given over to exploratory work and to the assembling of suitable material. A useful plan in my experience has been to assign to each student two problems, one involving laboratory work and often academic outlook which could be followed up at any time of the year, and the other an outdoor one of a seasonal nature. This has a certain insurance value from the point of view of results, and is particularly useful in helping to tide the student over the earlier slack and sometimes bleak phases of the work.

Teaching and research of the kind which I have been describing, helped by my natural inclination to these matters, have had the effect of bringing me into somewhat close contact with the practical grower and his problems. It happens also that, come of farming stock and am personally acquainted with many farmers and their ways of looking at things. I may therefore be allowed to put down some of my reflexions on the functioning of the research machine, and these will fittingly conclude this address. As there will be some criticisms, I wish to make it clear that henceforth I shall be speaking of plant pathology in the narrow sense where my own experience lies and where I am surer of my ground.

First of all there is the much-debated question of the relative importance of academic and applied research, not merely from the point of view of research as such, but also of research as leading to results of practical value. It has always seemed

e that, in discussions on this topic, much confusion thought has arisen from a more or less unconscious misuse of the rather numerous names which have been applied in this connexion. If we say that there are, broadly speaking, two types of research, the theoretical which aims at understanding phenomena without reference to any practical application of its findings, and the practical which aims at a definite practical result, there will, I think, be general agreement that both are important and desirable, and in many cases there will be found to be an interdependence between the two. Unfortunately it has been customary to apply a superfluity of names to each type of research, and the use of some of these names has led to misconceptions and, in my opinion, to some misdirection of research. Thus, the theoretical type is known as 'academic', 'fundamental', 'basal', 'long-term', and the practical as 'applied', 'ad hoc', 'short-term'. I would like to comment upon some of these terms.

If by 'fundamental' is merely meant 'theoretical' as roughly defined above, I have no objections to it. There is, however, a strong tendency to read a further meaning into the word. Just as a house cannot be built unless its foundations or fundamentals are properly laid, so, it is argued, must the practical work follow and rest upon the earlier fundamental investigation. One hears it freely stated that from such fundamental work results of practical importance drop out from time to time, and all that remains for the practical man is to recognize them as such or to seize upon certain principles, proceeding from which he can readily arrive at practical results. Now I am well aware that there is no great difficulty in furnishing examples in support of such views, more notably in certain physical arts—such as radio-communication—in which the practice has been built upon results which a few years ago were of theoretical interest only. The relation of the biological sciences to agriculture is, however, somewhat different, as I need scarcely enlarge upon. Most of the results of practical value have been obtained by the growers themselves—sometimes by accident—and in such cases the function of agricultural science has been in the main to explain the results, to point out their mutations and sometimes to indicate improvements. It is well to recognize the fact that results of the very greatest practical importance have been obtained in connexion with problems the theoretical basis of which is quite unknown to this day. For example, it has been possible to breed potatoes which to all intents and purposes solve completely the problem of late blight disease, and yet we are still quite ignorant of the theoretical basis of this very valuable result. Similar examples will no doubt occur to everyone.

It must not be thought that, in speaking as I have done, I am disparaging the theoretical type of research. I should be roundly accusing myself if I did so. It is obvious that theoretical research in biology generally, and in plant pathology in particular, has the same status as it has in any other science or form of learning—that it is worthy of being carried on, and carried on vigorously, on its own account. It has cultural value and adds its quota to the progress of civilization. It tends to fill out the general scientific picture, and from the point of view of the research worker himself it helps in many cases, if I may use the phrase, to keep his soul alive. It is, however, idle to maintain that practical results cannot be obtained without theoretical research, and it has always appeared to me that it is

undignified, to use a mild term, to put forward as a justification of theoretical research the possibility that results of practical value may arise from it by accident. No doubt if pursued long enough and with sufficient insight, it may point the way to a solution of all our practical problems, but that date is not yet. The practical method, I feel, must still be to tackle the practical problem with the means at one's disposal, and in so far as difficulties arise to refer these back for closer investigation in the hope that new insight may be obtained. In other words, the practical method should be that of direct attack, with theoretical research harnessed to it for purposes of guidance and further development.

The description 'long-term' as applied to theoretical research is appropriate. I should be happy to see it replaced by 'everlasting', for the more successful a piece of theoretical research proves to be, the more does it suggest further problems. On the other hand, I heartily deplore the tendency to apply the word 'short-term' to applied research. I have no objection to the phrase 'ad hoc', in so far as it means that there is a definite objective; but it is unfortunate that the adjective 'definite' is so often paraphrased to 'limited' and so to 'short-term', which in many cases has come to mean 'two years or thereabouts'—the normal duration of a research scholarship. The definiteness of an objective has no obvious relation to the time required to reach it, and in biological research, especially when its results are sharply conditioned by seasonal factors, it is surprising how long a time is necessary for the proper working out of even a simple problem. If, for example, it be the matter of the use of a fungicide, even when the best form of fungicide and the mode of its application have been settled, a great deal of work remains in testing its efficiency in various situations and over the variety of conditions which arise in a succession of seasons. I do not believe that the time-consuming nature of much applied biological research has been properly appreciated by those responsible for its organization, and to this more than to anything else is to be ascribed the fact that much research has failed to reach the farmer in a form usable by him. I shall refer to this point again.

The inadequate provision for the 'ad hoc' type of research is illustrated in another way. Fundamental research, from its long-term nature, and because it gives no promise of early results, is not the kind of thing which the cultivator could be expected to subsidize. It must rely therefore upon official support, and examples of reasonable support for it are familiar to all. On the other hand, it has often been expected that for work of the 'ad hoc' type, the industry concerned should pay a substantial share of the cost. This would seem on the face of it to be a reasonable arrangement, and it has in fact functioned, but there are inherent difficulties. Perhaps I can illustrate this point by an experience of my own. When an investigation of the carnation wilt problem had been in progress for two years, support for its continuation was sought from the carnation growers. Very naturally the lead was taken by certain members whose nurseries were at the time being seriously ravaged by the disease. Others, however, were as yet untouched and therefore not so interested. It was freely hinted that the trouble might not be a bad thing in itself, as tending to prevent overproduction and to weed out the inferior growers. Later, it may be added, the disease spread to other nurseries so that some growers had to change their

opinions. One grower said that he knew of a cure, and another that he did not propose to subscribe, but that he would pay for the cure when found. It so happened that there was present a man of very great importance in the industry who took the line that though his firm was not as yet seriously troubled by the disease, the industry as a whole was in danger, and it was highly desirable that he should have as much information as possible in advance of its coming. So the scheme came to be supported. I quote this example, not so much to illustrate how vexatious and chancy the initiation of research in this way may be, but to stress the fact that the financial interests of the growers of any one commodity are not necessarily identical.

Perhaps I should indicate here what, in my view, is the solution of this problem. The effect of the successful application of research to a problem of plant production is that the yield of produce of a certain quality is increased. This might lead either to a reduction in cost to the public, that is, to a raising of the standard of living, or to a reduction in the amount of land necessary for growing the required amount of produce, an economy which is obviously desirable in a small country such as Great Britain. In either event the advantage is national, and therefore the responsibility for initiating and supporting such *ad hoc* work should rest upon national funds, even though some growers may benefit, temporarily or permanently, from the results obtained.

I am hopeful that in the near future we shall see some improvements in the organization of plant pathological research. Hitherto, except for a few cultivations such as fruit, applied research has been of a very occasional and scattered nature. There has been little co-ordination, and, so far as I can see, a lack of purposefulness in following up the 'worth-while' problems to a stage where the results could be confidently brought to the notice of cultivators. It is the function of no one in particular to collate the work which has been done on a particular problem and to devise steps for carrying it forward to a practical solution. When such a survey is made, I am afraid that it will reveal a scarcity of practical methods of proved value, for the conditions under which much research has been done have been such as to limit its scope to purely mycological phases. I am not being facetious when I suggest that this state of affairs is reflected in the *abundance* of control measures which figure in plant pathological textbooks. I am quite certain that many of the methods put forward are of doubtful practicability or usefulness, and that very few have been worked out in a manner which would convince a practical man.

The number of problems awaiting a practical solution is so great that a rigorous selection would be necessary to allow of adequate attention being paid to those deemed most important. What we require is a 'priority list' of problems, and when such a list is drawn up, I hope that the views of research workers and growers will be sought more freely than has been the case in the past.

The practical aim of plant pathological research is not to study plant disease as such, but to point the way to growing good plants in spite of a liability to disease. It seems obvious, therefore, that research should be organized on a crop basis. There must be research institutes for the main crop plants, with small and possibly movable field stations where the more local problems can be investigated on the spot.

We have moved some distance in this direction and I think there will be a fuller development in the no distant future.

As regards the connecting link between research worker and grower, I speak mainly as a spectator. There is just one point which I wish to make in this connexion.

It has often been stated that research workers have in their possession a mass of information which the growers do not put to practical use, either because it is not brought to their notice at all, or if so, not in a form which they can understand. The blame for this tends to be laid upon the advisory organization. I would like to record what has been a frequent experience of mine when visiting nurseries in the Reading Province in company of the advisory mycologist. The object of the visit might relate to one particular problem, but by the time we had gone half-way round the nursery a dozen other queries had been put. There was obviously a multitude of problems, to many of which it was impossible to give a definite answer. Sometimes one could say that "Somebody in America had described a thing rather similar". The plain fact is that there are many growers' problems—of all kinds and dimensions—to which no clear answer can be given, because the necessary research work has not been done. This is a point which I have already stressed. Doubtless the advisory services could be made to function more efficiently—for example, by arranging better facilities for the demonstration of approved methods of culture—but I feel sure that, in the plant pathological field at least, the main lack is in the paucity of appropriate research, and not in the inability of the advisory services to convey such useful information as exists.

To sum up—there is no doubt as to the desirability and feasibility of tightening up our methods of training students for applied biological work, both in their undergraduate years and in their training as research workers, but I feel certain that the greatest requirement is a well-directed concentration upon the problems which the practical grower is prepared to put before the scientific worker. There are many such, and if, as appears to be very likely, there is to be a continued intensification of agriculture in Great Britain, there will be many more in the future. There is no doubt, therefore, as to the magnitude of the field and it is a responsibility devolving upon us, as scientific workers, to show that the practical problems of plant cultivation can be solved by the methodical application of the scientific method.

PSYCHOLOGICAL IMPLICATIONS OF THE CULTURE-PATTERN THEORY

AT the meeting of the British Psychological Society during April 5-10 in Exeter, a symposium was held on "Psychological Implications of the Culture Pattern Theory". The speakers were Lieut.-Colonel R. F. Barbour, Dr J. C. Flugel and Prof T. H. Pear.

Prof Pear opened by remarking that Rut Benedict's "Patterns of Culture" was now ten years old, it had affected some writers upon psychology who use the concept, but few attempts have been made to appraise the numerous psychological implications in the writings of Benedict, Margaret Mead, Bateson, Maslow and Clyde Kluckhohn in the

United States Perhaps on this side of the Atlantic, J H Waddington's "The Scientific Attitude" and O W Brogan's "The English People" can also be regarded as offering, consciously or unconsciously, many examples of 'culture-patterns'.

The theory may help to reconcile certain conflicting opinions in sociology, ethnology, psychology and economics. It maintains that the customs, institutions and dogmas of a culture are woven into a more or less coherent 'pattern'. Every society utilizes only a certain selection of the motives to which men may respond and the goals towards which their behaviour may be directed. The particular selection that any one society employs may be said to give it its characteristic 'pattern'.

Of 'culture', Kluckhohn offers this working concept: "all those historically created designs for living, explicit and implicit, rational, irrational and non-rational, which exist at any given time as potential guides for the behaviour of man." Linton's distinction between explicit and implicit culture is useful here.

Explicit culture comprises "all features of a group design for living which might be described to an outsider by participants in the culture". It includes not only external objects but also manifestations of feeling and thought. An observer ignorant of cricket could describe its apparatus, as well as the fact that the interruption of an exciting innings by the tea-interval is taken for granted by English, and puzzles or infuriates American, spectators. Implicit culture is "that sector of which members of the group are unaware or minimally aware". An MCC member might deem it unnecessary even to justify the tea-interval. Assumptions underlying the present ways of staffing the Foreign Office, or of granting army commissions fifty years ago, are unlikely to be stated easily by those who have always taken them for granted.

Kluckhohn defines two kinds of *patterns*, which he distinguishes from *configurations*. The *ideal pattern*, if described, conveys an idea of what, in a defined situation, people would do or say if they conformed completely to ideals accepted in the culture. For example, in stating the pattern "more than three persons waiting for a bus form a queue", the degree of deviation of actual cases of relevant behaviour from the ideal may not matter. But in a *behavioural pattern* attention is focused upon some mode of what people in fact do. The concepts are to some extent mutually dependent. Some criticism directed against Ruth Benedict's book is based upon the premise that she is writing about behavioural patterns. It is objected that she has not counted cases to establish statistical norms of behaviour, and has neglected material which does not fit her leading ideas. But, says Kluckhohn, 'she is not so much interested in an inductive analysis of how the Zuni, for example, do behave in fact, as in suggesting a relationship between accepted standards of behaviour in Zuni (ideal pattern) and cultural configurations of which the Zuni are largely unconscious'. A *configuration* is a concept of a higher order of abstraction than a pattern. Configurations are Sapir's "unconscious systems of meaning" and Benedict's "unconscious canons of choice".

A pattern is a generalization of behaviour or of ideals for behaviour. A configuration is a generalization from behaviour. Patterns are forms, configurations are interrelations between forms. A pattern can be defined by listing the parts in a determined sequence, and perhaps indicating the duration or

accentuation of each (as in music). A configuration (as in music too) states the principle behind a group of patterns, it is implicit in them and must be inferred out. Into Benedict's scheme, says Kluckhohn, even ideal patterns enter less than do configurations. She comes nearer to dealing with the 'whyness' than the 'whatness' of a culture. When she designates both types of pattern and more than one type of configuration by the same term she invites confusion.

Illustrations of the above concepts were given by Prof Pear. The Christian religion (Protestant and Catholic) shows behavioural patterns, ideal patterns and different, sometimes conflicting, configurations. The relative mildness of class enmity in England may be due to the fact that many important configurations, for example, 'fair play', respect for personalities, are common to different social strata and that others which are not, conflict less violently than in many other countries. He suggested that the culture-pattern theory, perhaps with these modifications, illuminates the following developments in psychology (among others):

Psychological provincialism Some psychologists have tried to build up 'the science of behaviour of the normal adult' upon the basis of observations and experiments confined very largely to college students in Western cultures. Mass observation and participant observation (functional penetration) have attempted to remedy this.

Some differences between psychological systems in the last fifty years may be due to the different culture patterns in which the authors grew up and lived. Examples given were James, Watson, McDougall, Freud, Jung and Adler.

The theory seems compatible with Prof Gordon W Allport's concepts of the transformation and functional autonomy of motives, put forward in his "Personality" and other publications.

Personality obviously depends upon culture pattern, and since there may always be with us the two opposed but complementary views of personality, one from the point of view of the 'actor', the other from that of the 'reactor', a study of culture-patterns will illuminate the way in which a judgment of a personality may cast at least as much light upon the judge as upon his 'subject'.

The difference between biological adaptation and mere temporary adjustment to the (often transient) claims of society is understood better by the help of this theory.

To what extent is the modern psychiatrist dependent upon the culture-pattern which 'employs' him? Must his tenets be fundamentally modified if it alters (for example, from a war-like to a peaceful set-up), or if he changes the country in which he works? To what extent does a psychiatrist on joining the combatant forces in any country accept the patterns and configurations of the new temporary 'culture'? How far do sentiments, ideals and purposes similar to those in the Allied armies actuate German army psychiatrists? Are their motives essentially different, and/or are they woven into a different 'pattern'? Would German army psychiatrists, for example, concur in certain English or American diagnoses of Hitler's mentality made *in absentia* and at a range of six hundred miles? To what extent are these diagnoses absolute or relative to certain postulated social norms?

Does a psychiatrist's own social, economic, religious, moral, political conditioning affect his

attitude towards a psychoneurotic (a) civilian, (b) soldier? Are some psychoses merely culturally defined, setting problems merely in social pathology? Are some psychoses constant all over the world?

May the success of the physical sciences have brought about a 'scientific attitude', which itself symbolizes a powerful culture-pattern? Is this in its turn now changing from respect for 'science' and its postulated 'freedom' (among educated people) to an overt opposition between this attitude, or sentiment, and one of doubt whether after two wars which men of science have made more deadly (perhaps made possible) the average individual scientific worker can any longer be blindly trusted to choose his problems? Nazi 'medical' investigators have betrayed humanity's trust in them. Can the ordinary man be blamed for reluctance to believe in the humanitarian bent of a man of science, merely because he calls himself by that name? (The broadcast discussion between Bertrand Russell and J. B. S. Haldane on May 4 (*Listener*, May 16, 1945) mirrors a clash of contemporary culture-pattern.)

Dr J. C. Flugel pointed out that the distinctions between behavioural patterns, ideal patterns and configurations, though useful and important, are not clear-cut, and shade into one another. They all involve a greater amount of inferential supplementation than do perceptual *Gestalten*. As with the latter, we must beware of confusing the subjective pattern itself with the reality underlying it. There are two problems, one purely psychological. "How does the pattern arise in the observer's mind?" and one metaphysical. "How far does the apprehended pattern (usually no more than an interconnected set of 'generalizations') correspond to actual fact?" In the latter problem we are confronted with the same tasks as those connected with the validation, and interpretation when validated, of hypothetical 'types' or 'factors'. The doctrine of culture-patterns is made more difficult by the fact that, especially in complex societies, the various patterns that can be distinguished (of group, locality or time and of varying degrees of inclusiveness) have complicated inter-relations. This may in practice greatly reduce the utility of 'patterns' as instruments of scientific thought.

Nevertheless the doctrine is valuable, as emphasizing social, contrasted with biological, explanations, as stressing the interrelations of the different elements of a culture, as producing useful working hypotheses and as raising many important problems (for example, its apparent opposition to the doctrine of 'archetypes', to psycho-analytic interpretations of culture and to the whole trend of thought of the 'classical' school of Tylor, Frazer, etc., as well as to the assumptions underlying the more recent work of J. D. Unwin).

Lieut. Colonel Barbour mentioned as a smaller but equally important problem, 'professional patterns'. Of the following he had had recent personal experience—boot operatives, hairdressers, psychiatrists. He asked whether psychologists tend to conform to some dynamic personal pattern. Is it easier for them to perceive the truth if it lies in one direction rather than in another? What is the bias of the observing, dissecting, enumerating mind?

Psychiatric diseases are still in the main defined in terms of inadequate performance of a human being *vis-à-vis* other human beings. In this War, psychiatrists when working as selection officers have developed a technique quite different from the

clinical interview, where the medical man tends to be an inquiring, almost aggressive figure. In selection, he has to be more passive and receptive. He substitutes for the negative aim of discovering discords the positive one of evaluating all sides of the personality.

Being conscripted into the Services involves for most men and women what is tantamount to a change of culture, exchanging a personally determined, family-oriented existence for a regimented community life, lacking in privacy and comfort, with increased risks to health and life. He described how these changes of cultural environment affect the psychotics, the mental defectives, the psychopathic personalities, the psycho-somatics and the neurotics respectively. The battle incidents which precipitate many of the neuroses are horrifying only to our culture, but are a few phenomena, for example, the faint, symbolic of something more primitive, more remote?

Benedict stresses that culture need not be essentially repressive. Yet every society has its outcasts. It is culture which decides that a difference is a disability. In the last thirty years in England there has been a steady growth of the province of illness at the expense of that of ethics. Recidivism, sexual perversions, cowardice are now quite as likely to be looked on as evidence of illness as of criminality. It is a sign of the times—or of our culture—to send for the doctor or for the psychiatrist, where a generation ago the priest would have been called in. This is a change, possibly an advance, yet in another culture the teacher or politician might be consulted.

Lieut. Colonel Barbour concluded. "It is particularly appropriate that this symposium should be held at this time. During the last twenty-five years we have seen the rise of Nazism and a new phase of national development in Russia. It makes me hopeful of this country, as we too can change our culture if we so wish. But we must scrutinize very carefully what appear to be some dominant trends of our time, among them the evading of individual responsibility, a softness of outlook which seems to expect life to be free, even of growing pains, a preference for compromise rather than for co-operation."

¹ Summarized in "Are There Human Instincts?" by T. H. Pear, *Bull. John Rylands Library*, Manchester, 27, No. 1 (Dec. 1942).

X-RAYS AND CELLS

By DR. P. C. KOLLER
Royal Cancer Hospital, London

THIS year marks the centenary of the birth of Roentgen, who announced the discovery of X-rays to the Physico-Medical Society of Würzburg fifty years ago (1895). The importance of X-rays for diagnosis in medicine was quickly realized, but their use in treatment, owing to technical difficulties, began only after the discovery of radium three years later. First radium was found to check the growth of tumours in mice¹, then X-rays were found to check mitosis in roots and pollen², early discoveries, which form the remote foundation of modern radiotherapy, or radiation treatment. Later, Strangeways and his colleagues^{3,4} showed that different doses had different kinds of effects on tissue cultures.

Yet while the evolution of radiotherapy was analytical on its physical side⁵, on its biological side it remained empirical, for little or nothing was known

the way in which radiation exerted its influence on cells and tissues. To provide the required information many experiments have been and are being carried out on the 'biological effects of radiation', a phrase which seems to claim too much for data which tell little. Such diverse 'biological indicators' have been used as bacteria, infusoria, yeast and mould, corn and pondweed⁶, pollen, seed, root and stem of bean and onion, egg, sperm and larva of fly⁷ and arfish⁸, toe and heart of frog⁹, caterpillars and salamander, sperm of ram, blood of mouse, eye of cat¹⁰, and skin of man, indeed, a regular witch's brew.

The dose varied as much as the material, from 2.5 to 200,000 r. The results varied even more, often to the despair of the experimenters. This confusion and contradiction of data can easily be explained, for most of the effects measured and compared are not so immediate and initial effects but the end-products of a chain of reactions set in motion by the radiation. The length and complexity of these chains are unknown. While the effects induced were striking, owing no doubt to the too high doses of radiation used, their complexity made an analysis of their origin extremely difficult if not impossible. From many experiments on the biological effects of radiation two general conclusions were reached: that the effects were on the nucleus, and that their expression was delayed.

A new insight became possible with the discovery that radiation induces gene mutation¹¹ and breaks in the chromosomes¹². Investigations by Muller¹³ and Hers^{14,15}, using the sperm of *Drosophila*, showed a quantitative relationship between single ionizations of the chromosomes and the changes they induce. The analysis of the end-results of two such changes, even as chromosome rearrangements, in the giant parter-millimetre chromosomes of the salivary glands of *Drosophila* gave brilliant results¹⁶. But this success was limited by the fact that the structural changes were available for analysis only in the generation derived from X-rayed sperms, and these changes represent only a small fraction of those originally induced. Cytologists thereupon turned their attention to the direct study of X-rayed cells.

The advantage of their study is that the different changes in the chromosomes can be seen a few hours after treatment and the method of their origin can therefore be inferred. During the last eight years a great body of data has been obtained by Sax¹⁷, Hatcheside¹⁸ and others using pollen-grains—single cells, which are also individuals with a fixed cycle of development. This new work confirmed the first principles established by Stadler¹⁹ and Mather and Stone²⁰, that breakage and reunion were separate events and that breakages were of two orders—chromosome and chromatid—and the time the chromosomes split in the resting nucleus thereby established. Koller²¹ showed that the death of the cell was the result not of direct action by X-rays but

loss of chromosome fragments at the ensuing mitosis. Again, however, it soon became evident that the interpretations of different workers were inconsistent. This could be attributed partly to differences in interpretation of the induced chromosome changes and partly to inherent shortcomings in experimental design. Most of the cytological analyses of the radiation-induced changes disregarded the enormous variation in breakability of chromosomes during the nuclear cycle and the great differences in rate of development of cells within any sample. Besides these two, lack of temperature

control—which characterizes most cytological analyses—introduced a third error. Furthermore, the two most important events, breakage and reunion of broken chromosomes, although known to be separate events, have not been separated. The situation, indeed, sometimes showed signs of approaching insolubility, though concealed with higher mathematics.

A fresh approach to this problem is made by Darlington and La Cour²² based on an analysis of spontaneous chromosome changes²³. Their methods are new in several respects. Radiation effects are analysed in samples of complete cells in complete developmental series—root-tips, pollen grains and pollen tubes with resting stages lasting from a few hours up to 195 days. The breakage and reunion of chromosomes are recorded separately. Doses as low as 5 r and up to 360 r are used over a wide range of controlled temperatures. The statistical analysis, to which Mather has contributed, proceeds from frequencies to coefficients and correlations both new and unexpected. One simple example will show how these methods have brought order out of confusion. For many years it has been a moot point whether chromosome aberrations varied proportionately to, or according to some other power of, dose, and if the latter whether with a 1.5 power or with the square or with some other exponent. Now Darlington and La Cour have shown that breaks vary directly with dose, taking an average of total cell samples. Reunion of broken chromosome ends, on the other hand, varies with breakage, taking not whole cell samples but cells in classes with different numbers of breaks. One realizes, therefore, the hopelessness of the previous search for simple numerical formulae.

These new methods of Darlington and La Cour seem to have been successful in separating the nuclear and cytoplasmic effects and in showing their interactions. The main conclusions reached are: (a) that breakability and rejoinability of the chromosomes are negatively correlated, (b) that variation in both depends on the activity of the cell and on the heterochromatic content of the nucleus. These correlations lead the authors to assume a common denominator in the three classes of effects—breakage, reunion, and sister reunion of chromosomes and chromatids. So much they seem to have proved, whether they are justified in supposing that this common denominator is the nucleic acid charge on the chromosomes further studies will show.

There is an interesting analogy between the primary effects of low-dose irradiation as described by Darlington and La Cour and the characteristic abnormal mitosis in tumours²⁴. Both show a prophase hastened (not, as other workers have said, retarded); an excess of ribose nucleic acid in the cytoplasm²⁵; and an excess of unpolymerized or sticky desoxyribose nucleic acid on the chromosomes²⁶.

Darlington and La Cour's results confirm some of the principles deduced from previous experiments. They seriously conflict with others for reasons which their new data make clear. They prove that irradiation, as well as temperature, affects the time-scale of development by which we have to measure its action in the breakage of chromosomes. This explains clearly why single-time comparisons of radiation effects (often with uncontrolled temperatures and incomplete recording) have hitherto shown discordant results. Their results show also the complexity of cell-response to radiation, which, however, can be revealed and analysed by the methods used.

Apart from the theoretical conclusions which Darlington and La Cour arrive at, their method of analysis (which they amply illustrate) will now enable us to investigate and to compare the effects of radiations of different wave-lengths (X- and gamma-rays, neutrons and alpha-particles), and that of different dosage-rates, all of which are of great importance in the development of radiotherapy. The misgiving has often been felt, and quite recently expressed in *Nature* by a physicist²⁷, "that there is an uncertainty about the action of X-rays which is very tantalizing. Complete success appears to be so near and yet continues to elude us". We now have, if not success, at least the prospect of success. The experiments of Darlington and La Cour give not only a new impetus to the study of the biological effects of radiation, but also a new foundation.

THE BELGIAN NATIONAL FUND FOR SCIENTIFIC RESEARCH

By JEAN WILLEMS, C B E

Director of the National Fund for Scientific Research

ON October 1, 1927, King Albert spoke on the occasion of the 110th anniversary of the creation of the Cockerill Works at Seraing, at the very centre of the industrial district of Liège. "Nations," he declared, "which neglect science and scientific men are marked for decadence. Considerable and sustained efforts must be made, there must be more initiative if we wish—as we must wish—to maintain our position and our reputation. To-day, those who do not go forwards go backwards."

This speech was made less than ten years after the conclusion of the War of 1914-18, when the "Fondation Universitaire", as well as the funds of the various Belgian universities, had been richly endowed, following the winding up of the Commission for Relief in Belgium and of its Belgian counterpart, the "Comité National de Secours et d'Alimentation"

It emphasizes the pressing demands made by science and the continual expenditure which has to be faced for the maintenance of intellectual standards. King Albert's urgent appeal received a generous response and three months later public subscription had provided Belgium with 115,000,000 francs. This led to the creation, on April 27, 1928, of the "National Fund for Scientific Research", which aimed at intensifying scientific activities, and at placing research workers and scientific men in such a position that they could play a worthy part in the moral and material development of the country.

The new institution benefited immediately from the active co-operation of the most eminent representatives of the academic world. Its programme of activities included all questions which had necessitated and justified its creation, and it soon appeared that the measures adopted justified the highest hopes. At first, however, the National Fund was scarcely known outside Belgium. It suddenly came to general notice when it assumed responsibility for a perilous venture which was eagerly followed all over the world. This was the first stratospheric ascent by Prof Piccard. Within three days, this man of science achieved popular renown. Homage was paid to him at a scientific meeting, when Prof Bordet himself a Nobel prizewinner, said "Your exploit which has thrilled men of science, has gone straight to the heart of the people. They are filled with admiration when they see a man of your intellectual power championing the cause of science with the courage of a hero."

The National Fund was applauded for its share in this work, which proved its desire to promote active international science.

This favourable impression was confirmed by the archaeological excavations pursued at Apamea. One of the immense porticos which stood above the highway of this wealthy Syrian city, once a rival of Antioch, was partially reconstructed. Apamea was plundered and burned by the Persians in the seventh century B.C., but the discoveries made among its ruins have revealed original works of art and architecture, and particularly wonderful mosaics. The remains, now in the museums of Brussels, enable us to recapture some of the features of the ancient Persian and Roman town. The names of the Belgian historians and archaeologists, Henri Pirenne, Franz Cumont and Fernand Mayence, are associated in this fine work.

Equally valuable results of another expedition supported by the National Fund are also gathered together in the Brussels Museums of Art and History. The expedition went to Easter Island, in the Pacific Ocean, and investigated the enormous statues carved in the rock, reaching heights of 6-30 ft., and weighing up to 40 tons. A Franco-Belgian mission, including M. Henri Lavachery, now keeper of the Royal Museums of Art and History, undertook the journey and succeeded in gathering valuable information on a most interesting problem. This was to discover whether the writing known by the natives of the island in the fourteenth or fifteenth century could be identified with that shown on slabs discovered in India, and dating as far back as 2,500 B.C. From this it was hoped to ascertain whether Easter Island was the remainder of a lost continent and of a rich civilization since vanished.

Another expedition sponsored by the National Fund was equally successful. Ruwenzori had first been seen by Stanley in 1888, and since then its east-

slope had been explored several times, the highest summits having been climbed for the first time in 1906 by the Duke of Abruzzi. But the western slope had remained unexplored. This part of the mountain lies within the boundary of the Belgian Congo, and the Belgian mission undertook to study methodically its geology, flora and fauna. Thanks to their skill and endurance, the expedition gathered much information, and hoisted the Belgian flag at an altitude of 15,000 ft.

About the same time other men tackled, with great devotion, a problem which combined scientific and humanitarian interests. For a long time, Belgian missionaries had pursued their work in certain parts of China. One of them, the Rev. Father Rutten, returned to that country accompanied by two medical men, and undertook long journeys to vaccinate missionaries. Their aim was first to check, in endemic conditions, the preventive methods advocated by Dr. Weigl, the Polish man of science, and secondly to test the curative value of a serum in cases of exanthematic typhus. The results obtained are well known, whereas in former years the Belgian community of Scheut lost a number of missionaries, no case of disease was recorded after vaccination, but the same mortality prevailed in the missions where vaccination had not taken place. These results were published by the French bacteriologist, Charles Nicolle, and by Prof. Bruynoghe, of the University of Louvain.

Belgium also took part in the organization of the International Polar Year (1932-33). Ever since 1882-83 the idea had been mooted of active co-operation of scientific workers belonging to various countries in order to bring more unity and co-ordination into the work of polar expeditions. The programme of the second Polar Year, prepared a long time ahead in the course of international conferences, included a great number of subjects: the meteorology and explorations of the atmosphere, the dynamics of cyclones and anti-cyclones, weather forecasts, terrestrial magnetism and atmospheric electricity, earth currents and the aurora polaris.

Under the auspices of the Government and of the National Fund, Belgium undertook to establish a new magnetic station in the province of Liège and another in the Belgian Congo. These stations carried on observations, following the plans elaborated by the Polar Year Commission. The president, Prof. La Cour, director of the Copenhagen Observatory, paid tribute on several occasions to the part played by Belgian scientific workers in the common effort.

A few other examples of the activities of the National Fund can only be mentioned: participation in the new scientific station established on the Jungfrauoch, in the work of the Commission of New Analytical Reactions and Reactives, created by the International Union of Chemistry, in the works of the International Office for the Protection of Nature.

Then came the War and the German occupation. The country was separated from the civilized world and endured with great courage and devotion the oppression and sufferings of this cruel ordeal. Her men of science and research workers resisted to the end. When one university was closed by the occupying Power, other universities and institutions received its professors and students. When one institution lacked some product or apparatus, other institutions gave them or lent them. When some professors or academic authorities were arrested or dismissed, their

colleagues filled the gap. Without publicity, the National Fund applied itself to the task of helping, promising young men of science and research workers and of solving questions arising from war conditions such as the scarcity of food, and the protection of the unique stained glass windows of the Church of St. Gudule in Brussels. It has also prepared the ground for attacking post-war problems, within the framework of its traditions. All this necessitates inroads on available resources, and great tenacity in spite of unfavourable and often hostile surroundings.

To-day Belgian scientific workers are once more free to speak and act according to their scientific conscience. Contacts have already been established with their foreign colleagues, publications have been exchanged, and visits abroad are being planned. The joy derived from this release can only be appreciated by those who have for years been 'in prison' in an occupied country. We are beginning to hear of the eminent part played by men of science during the War. They will work to-morrow with the same zeal to further the material and moral reconstruction of the world. The National Fund for Scientific Research will continue to support Belgium in the part she is going to play in this great work.

OBITUARIES

The Right Hon. the Earl of Onslow, P.C., G.B.E.

LORD ONSLOW died, after a long illness, on June last. He was a man of many parts, many corresponding activities and many friends, who were attracted to him by his own native friendliness and the affectionate simplicity and sincerity of his disposition. His many public services, in the course of which he left his mark especially on the day-to-day administration of local government, are a matter of record. He rendered other services which are perhaps, less widely recognized, though, regarded in their true perspective and in the light of the fruits they may be expected to bear hereafter, they may prove to be the most important of them all.

A sportsman, and, like most of that fraternity, field-naturalist, Lord Onslow became, as a matter of course, a fellow of the Zoological Society, and, after many years of useful service on the Council, was elected president in 1936 as the obvious successor to the late Duke of Bedford. To this new task he brought the high sense of duty and the unflinching industry which characterized all his undertakings. He had, already, in 1926, been chosen as president of the Society for the Preservation of the Fauna of the Empire. In this post he was in his element, and it was here that he did what may well prove to have been the most enduring and most valuable work of all. To him the preservation of wild life meant the preservation of the beautiful and interesting thing the contemplation of which above all makes human life worth living. He recognized as few others did that man, "a little lower than the angels", was also only a little higher than the rest of the world ecology of which he is a part, and incomplete if divorced from that ecology. Further, he recognized that though man could destroy, and was, on balance, destructive rather than a productive animal, he could not create. If man destroyed a species, it was lost for ever, and man might discover too late that he had done himself irremediable harm, and whether

the damage done by the destruction of a species could be measured economically or not, at least, through his agency, life on this planet had been made less beautiful and less interesting, if not for everybody, at least for many of its human inhabitants.

It may well be that the first seeds of this conviction were sown in Lord Onslow during a period of his early life spent in New Zealand, where his father was Governor, and was one of the first to initiate practical measures to avert the destruction of New Zealand's unique avi-fauna. The indifference of New Zealanders to the marvellous ecology of which they became the trustees by right of settlement always distressed him. Having, as president of the Fauna Society, taken the leading part in securing the adoption of the convention for the Preservation of Wild Life in Africa, he turned eagerly to preparations for a new conference through which he hoped to extend the application of the principles embodied in it to south-east Asia and Australasia. That Conference was to have been held under his presidency in 1939, but the threat of a world war led to its postponement.

Throughout the War, he never lost hope of an active renewal of the campaign for wild-life preservation, which he hoped to see extended ultimately to the whole world. He watched with critical interest the negotiations of the Pan-American Conference in 1940 which led up to the convention for "Nature Protection and Wild Life Preservation in the Western Hemisphere" between the United States and the South American republics. He used unavailingly all the influence he possessed to induce the American States to invite representatives of Canada and other British and European-owned territories in the American Continent to the Conference, and was not a little exasperated by the illogical insularity which led the United States and the rest to exclude them. Nevertheless, he had the satisfaction of observing that the Convention agreed to follow in essentials the model of the African Convention of which he was the legitimate parent, and he was determined that American observers should be invited, for their better education, to the postponed Conference for south-east Asia and Australasia when summoned after the War. He was keenly interested, also, as was to be expected, in the movement for the establishment of national parks and nature reserves in Britain, and was a most active president of the Society for the Promotion of Nature Reserves.

It may be said of Lord Onslow that he saw the light and, very clearly, the vision which the light revealed. In failing health he never lost interest in the work of the Society for the Preservation of Fauna of the Empire, and probably few events gave him greater pleasure than the presentation to him in November last of the first gold medal of the Society in recognition of his outstanding services to the cause of fauna conservation. It will not be easy to find a torch-bearer to succeed him, one who will feed the flame as he fed it, and bear it blazing bright with the same resolute and lofty inspiration.

HENRY G. MAURICE.

Dr. Hans Przibram

THE obituary column of *The Times* records the death "some time in 1944, at Terezin (Theresienstadt), Czechoslovakia, of Hans Przibram, formerly Professor in the University of Vienna, and his wife Elizabeth Margarethe (née Ruhmann)." Behind these

words lies untold tragedy, for Theresienstadt was one of the worst of the concentration camps, and many thousands of Jews were slaughtered there. The War had not long begun when we heard of the death at Dachau of Prof. M. Siedlecki of Cracow, an old and famous and much-loved naturalist, it is scarcely ended when we hear that Hans Przibram has been done to death, who once was rich, enthusiastic, hospitable, and whose Laboratory, or "Vivarium", was known to every naturalist who came to Vienna. We know of many another, and dread to hear of more, who have suffered from the same ferocious inhumanity.

Hans Przibram began his work about forty years ago, under the influence of Wilhelm Roux, Jacques Loeb and Hans Driesch, in other words, he became a student of experimental zoology. He planned an ambitious work under that title, and brought it out between 1907 and 1914, in five parts, on "Embryogenese", "Regeneration", "Phylogenese", "Vitalitat" and "Function". An early paper of his, on the "Anwendung elementarer Mathematik auf biologische Probleme", appeared in *Roux's Vorträge* in 1908, and fifteen years later he published an "Aufbau mathematischer Biologie", in *Shkuel's Abhandlungen*. Another book of his, published in 1922 after he had become *ausserordentlich* professor of experimental zoology, was entitled "Form und Formel im Tierreiche", or "Beiträge zu einer quantitativen Biologie". It contains many useful numerical data, physiological and morphological, or "biological constants" as he chose to call them. The new science of biometry was after his own heart, and he published various "Messungen und Wachstumsmessungen", chiefly among insects. These measurements, especially those on one of the praying mantids, led him to believe (as Brooks and others had suggested before) that the spurts of growth and successive moults of an insect tended to coincide with a doubling of its weight and (presumably) with a histological duplication of every cell in its body, and further, that the doubling of its weight implied a linear increase from one stage to another in the ratio of $1\sqrt[3]{2}$, or $1\frac{1}{2}6$. The sizes of the successive chambers in a spiral foraminifer should, and do (he said), follow the same law, but the study of the cast skins, or successive moults, of a serpent led to no such result, for no general histological duplication was involved. There was a good deal of truth in all this, but Przibram was apt to go too far, and let his theories outstrip his facts. It is at least clear that he was a keen and early student of that experimental side of zoology which has proved engrossing ever since to many.

Hans had a brother Karl, a distinguished physicist, we have no news of him. He wrote, among other papers, some on the Brownian movement, which I remember attracting Sir J. J. Thomson's attention to when they appeared. One was on the Brownian movement of non-spherical bodies, and another (in *Pflügers Archiv*) on the Brownian movement as indicated in the movements of minute organisms. He also wrote a curious paper on "Form und Geschwindigkeit ein Beitrag zur allgemeine Biologie".

D'ARCY W. THOMPSON.

We regret to announce the death of Lord Eimouth, who during 1897-1911 was a member of the chemical staff at Columbia University, or June 7, aged eighty-two.

NEWS and VIEWS

Award of Bruce Medal to Prof E. A. Milne

THE Bruce Gold Medal, founded in 1897, is unique among astronomical awards in that the responsibility for the nomination of candidates rests with the directors of the Harvard, Lick and Yerkes Observatories in, and the Greenwich and Cordoba Observatories outside, the United States. The consequence has been that the directors of the Astronomical Society of the Pacific, who are the trustees of the Bruce Medal Fund, have always had before them the names of the outstanding astronomers of the time, and so wise has their final choice always been that the Medal is generally recognized as the highest award for astronomical achievement. It is only fitting that the name of Edward Arthur Milne should be added to those of the great mathematical astronomers—Newcomb, Hill, Poincaré, E. W. Brown, Eddington, de Sitter and Charlier—who have achieved this distinction. Milne's contributions have covered a wide field in astrophysics and cosmogony. His studies of radiative equilibrium in stellar atmospheres greatly extended and deepened the classical results of Schwarzschild in this field, while the collaboration of Milne and Fowler in the application of ionization theory led to the generally accepted scale of temperatures and pressures in the stellar sequence. By-products of these two main lines of investigation were a theory of the equilibrium of the solar chromosphere as a result of monochromatic radiation pressure, and the concept of 'run-away atoms' as the carriers of those disturbances in the sun which lead to terrestrial magnetic storms and radio fade-outs.

Milne's recent work has traversed more controversial ground. On one hand, he has dealt with the consequences which flow from the role of photospheric opacity on the internal structure of the stars, and on the other hand with the kinematic aspect of the apparent recession of the extra-galactic nebulae, treated in the first instance as actual motions in a flat Euclidean space. The attempt to introduce dynamics and gravitation into this concept of world-structure has led to the distinction between the finite t -time by which the observer on a 'fundamental particle' describes events, and the τ -time with an infinite past with which events may be described in a public hyperbolic space. No matter what the ultimate success of these later ventures, there can be no doubt of the clarification in our ideas which has already resulted from his work, or of the courage which this single-handed attack upon these great problems must have demanded. The award of the Bruce Medal is therefore but a fitting recognition of Prof Milne's great contributions to our knowledge of the stars, and of that larger system of which the stars form a part.

Guthrie Lecture of the Physical Society:

Prof. Arturo Duperier

THE Guthrie Lecture of the Physical Society will this year be given by Prof Arturo Duperier on July 6 at the Royal Institution, his subject being "The Geophysical Aspect of Cosmic Rays". As research professor in the Instituto Nacional de Física y Química (Rockefeller Foundation), Madrid, Dr Duperier made experimental studies in magnetism in association with his former teacher, Prof Cabrera. Later, in 1932, he was appointed professor of geo-

physics at the University of Madrid. His geophysical researches included studies on meteorology, atmospheric electricity and cosmic radiation, papers on these subjects were published during the Civil War, in the course of which he paid two visits to Great Britain, the victory of Franco occurred during his second visit, and he has since lived and worked here. In association with Prof P. M. S. Blackett he continued observational work on cosmic rays at Manchester, with the aid of a research grant from the Royal Society, later he transferred his apparatus to the Physics Department of the Imperial College, London, where he has worked for several years. His observational discoveries include remarkable occasional changes of cosmic-ray intensity associated with geomagnetic storms.

British Coal Utilisation Research Association:

Prof. D. T. A. Townend

PROF D. T. A. TOWNEND, Livesey professor of coal, gas and fuel industries at the University of Leeds, has been appointed director of the British Coal Utilisation Research Association. Educated at Bancrofts School, Prof Townend held an exhibition at the East London (now Queen Mary) College, where, after war service, he graduated in 1920. Following post-graduate study in fuel and chemical engineering at the Imperial College of Science and Technology, he was associated there for many years with the late Prof W. A. Bone and Prof D. M. Newitt in investigations into combustion and high-pressure problems, and held successively a Salters research fellowship and a Rockefeller international research fellowship. He is a leading author in the field of combustion, and in 1933 discovered the two-stage ignition phenomenon of higher hydrocarbons, etc. The Livesey chair which Prof Townend has occupied for seven years was endowed by the gas industry in 1910, since when the Department has collaborated closely in research with this industry. Prof Townend has served on the Council of the Gas Research Board since its inception in 1939 and is an honorary member of the Institution of Gas Engineers, he is also chairman of the Yorkshire Section of the Institute of Fuel. During the War he has served on a number of Government committees and his Department has made notable contributions to the war effort.

Visit of Prof. A. V. Hill to Denmark and Norway

PROF A. V. HILL, senior secretary of the Royal Society, is visiting Copenhagen to convey the greetings of the Royal Society, as representing the men of science of Great Britain, to their colleagues in Denmark, and through the Academy of Sciences in that country to discuss with them what aid British science can give to the rehabilitation of science and scientific education in their country. After three days in Copenhagen, Prof Hill will proceed to Oslo for the same purpose. An extraordinary meeting of the Norwegian Academy of Sciences has been called to meet him. It is hoped that these visits will do much to enable both the Danes and Norwegians to re-establish the firm scientific contacts which, until the occupation of their countries by the Nazis, they have always maintained with men of science throughout the world.

Destruction of Scientific Institutes in the Philippines

INFORMATION has been received that the buildings of the Bureau of Science, Manila, have been utterly destroyed in the fighting for that city, and, moreover, it is reported that the Japanese have destroyed the Philippine College of Agriculture at Los Banos, eastward of Manila. The loss of the scientific collections and libraries in the Bureau of Science is irreparable. The Bureau took shape in January 1906 by the union of the Bureau of Government Laboratories and Mines, and was charged with investigations in bacteriology, immunity, prophylaxis, etiology, botany, various branches of zoology (in particular entomology), technological chemistry, geology and mining engineering. The whole structure has gone—the records of the work of forty years, for the two Bureaux named had been at work for four years before the Bureau of Science was formed.

Botany has been singularly hard hit and singularly ill-fated in the Philippines. The collections which Sebastian Vidal made when he was inspector of forests towards the end of the Spanish regime were lost in an accidental fire in 1897, and those of the Augustinian Friars burned when the Guadalupe Monastery was destroyed in the fighting in 1899, in consequence of this, Dr E D Merrill, who went to Manila in 1902 as Government botanist, had to begin his work without foundations on the spot. He gathered together a herbarium unique in its facilities for study of Philippine botany and a botanical library second to none in Asia. These have gone. His four-volumed "Enumeration of Philippine Flowering Plants" (1922–26) preserves a part of the records, but beyond collections from the islands, the herbarium held a great amount of comparable material from all parts of the East.

Spectroscopically Standardized Substances

As the use of the spectrograph for the detection and determination of the metallic elements in all kinds of materials increased, there arose a demand for extremely pure metals, oxides and salts to serve as standards. About 1922 Dr S Judd Lewis suggested to Messrs. Adam Hilger, Ltd., that they should supply for this purpose spectroscopically standardized substances, the proposal was adopted, all arrangements for the supply of the substances and their analysis being in the hands of Dr Judd Lewis. These pure substances have become well known under the trade mark of "H. S." Substances, and now include most of the more common and many of the rarer metals, as well as most of the rare earth oxides. In 1932, when Dr Judd Lewis proposed the 'ratio quantitative' method of spectrographic analysis, the 'Specpure' series of 'ratio powders', 'ratio solutions' and pure salts was introduced, and now comprises more than fifty substances which are available in a spectrographically standardized condition. Every supply of "H. S." or "Specpure" material has always been accompanied by a full report of the results of chemical and spectrographic examinations made on that material. So far as possible, an estimate is given of the amounts of each trace element present, and reference is made to all the spectrum lines due to the impurities which have been detected.

In view of the ever-increasing demands for the substances included in these two schemes and for new additions to the list, the need arose for additional manufacturing and analytical facilities. Messrs

Adam Hilger, Ltd., have therefore entered into an agreement with Messrs Johnson, Matthey and Co., Ltd., whereby the latter will in future undertake the supply of these substances and the control of their purity at their Research Laboratories, Wembley, Middlesex, where many of them will be made. Dr Judd Lewis, who acted as consultant for Adam Hilger, Ltd., for many years and was chiefly responsible for the development of the "H. S." and "Specpure" schemes, has been engaged in that capacity by Messrs Johnson, Matthey and Co., Ltd., and the staff of the Spectrographic Department of their Laboratories has been augmented by the appointment of Mr D M Smith, formerly in charge of spectrographic investigations at the British Non-Ferrous Metals Research Association. Future sales of "H. S." and "Specpure" substances will be made only by Messrs Johnson, Matthey and Co., Ltd., from their head office at 73–83 Hatton Garden, London, E C 1.

Official Topographic Maps

OFFICIAL large-scale maps are available for comparatively few parts of the world outside western and central Europe, including the British Isles, the eastern United States, India, much of Burma, several of the Netherlands East Indies and Japan. South America, Africa and Australia each have few areas of such detailed survey. In the April number of the *Geographical Review*, a coloured world map on a scale of 1 to 50,000,000 compiled by R R Platt shows the distribution of official topographic maps as available at the outbreak of war in 1939. It covers scales up to and including 1:253,440 (4 miles to 1 in). Three categories are recognized, scales of 1 mile to 1 in. or larger, those of 1–2 miles to 1 in. and those of less than 2 miles down to 4 miles. Under each category an attempt has been made to distinguish between maps based on topographic survey on which relief is shown by contours or hachures, and maps of less complete detail with relief shown by form lines or hill shading. As a general rule, only maps produced by States for their own territory are shown, but there are some few exceptions. Compilations produced by an official agency of one country in the territory of another are not shown.

Russian Papers on Pure and Applied Mathematics

AMONG Russian periodicals and books recently received are several containing papers on pure and applied mathematics. A striking feature is the many investigations of elasticity problems in *Applied Mathematics and Mechanics*. There are also many other papers of considerable interest, for example, the paper on the flow of a gas at supersonic velocities by V S Tatarenchik (*App Maths and Mechanics*, 8, 401, 1943), which should be compared with current investigations by Southwell and his colleagues (*Nature*, 154, 90 and 834, 1944). N N Painsky gives (*Astron J S U*, 21, '78, 1944) the result of calculations which support Russell's criticism of Jeans' theory of the origin of the solar system. In addition to the journals mentioned above, we have also received a valuable atlas of nomograms, containing thirty-seven plates. All the publications received are being deposited in the Science Museum, South Kensington, London, S W 7, where they will be available for anyone who desires to consult them. By the aid of the summaries in English or French,

t should be fairly easy for those entirely ignorant of Russian to understand the results and methods of the papers

Belgian Visitors to Britain

THE fourth group of distinguished Belgians to visit Great Britain as representatives of the Belgian Fondation Universitaire and guests of the British Council have arrived in London. They are Prof M Florin, Faculty of Science and Medicine, Liège, Prof F Albert, Faculty of Medicine, University of Liège, Prof F Bremer, Faculty of Medicine, University of Brussels, Prof A Castille, Faculty of Medicine, Louvain, Prof J C Firket, Faculty of Medicine, Liège, Prof H R. Fredericq, Faculty of Medicine, Liège, M Jean Willems, director of the National Fund for Scientific Research (see p 780), and Prof L M Gyselynck, Faculty of Law, Brussels. They are meeting leading British authorities in their particular spheres in universities and research institutions in London, Cambridge, Oxford, Liverpool, Edinburgh, Glasgow and Belfast.

University of London

PROF D HUGHES PARRY, University professor of English law at the London School of Economics and a member of the Senate since 1930, has been elected vice-chancellor for the year 1945-46.

The title of professor emeritus has been conferred on the following: Prof Major Greenwood, professor of epidemiology and vital statistics since 1926, Prof. William Wilson, Hildred Carlile professor of physics at Bedford College from 1921 until his retirement in 1944, Prof Harold Simpson, professor of mathematics at Bedford College from 1912 until his retirement in 1944.

Prof C Daryll Forde, since 1930 Gregynog professor of geography and anthropology at University College, Aberystwyth, has been appointed to the University chair of anthropology tenable at University College as from October 1, 1945.

The degree of D Sc has been conferred on Dr E T Davies (Birkbeck College), Dr F W Jane (Birkbeck College), Mr S G Soal (Queen Mary College), Mr A C Frazer (St Mary's Hospital Medical School), Mr L A Allen and Mr C G Johnson.

Summer School in Colloid Science

THE Birmingham and Midlands Section of the Royal Institute of Chemistry has arranged, in co-operation with the Departments of Colloid Science and Physical Chemistry of the University of Cambridge, a Summer School in Colloid Science in the form of two courses, extending from June 23 to June 30 and June 30 to July 7 respectively. The director of tuition for the School is Dr A E Alexander. Both courses are being opened by Prof E K Rideal, professor of colloid science in the University of Cambridge and president of the Society of Chemical Industry, and the opening lectures are by Dr W Clayton, on "Foods as Colloid Systems" (course A), and Dr E H Callow, on "Colloids in Theory and Practice" (course B). Some two hundred research chemists are attending the School.

The Night Sky in July

New moon occurs on July 9d 13h 35m, UT, and full moon on July 25d 02h 25m. The following conjunctions with the moon take place: July

5d 06h, Mars 3° N, July 6d 02h, Venus 0 4° N, July 11d 10h, Mercury 2° S, July 14d. 12h, Jupiter 4° S. Only one occultation takes place in July, 20 Ceti reappearing on July 30d 00h 37 7m, the time refers to the latitude of Greenwich. Mercury sets at 21h 26m, and 20h 22m at the beginning and end of the month respectively, attaining its greatest easterly elongation on July 23, and is not very well placed for observation during the month. Venus is a conspicuous object in the early morning hours, rising at 1h 30m and 1h 08m at the beginning and end of the month respectively. Mars moves from the constellation of Aries into Taurus during July and rises at 0h 53m on July 1 and 23h 18m on July 31. Jupiter sets at 23h 15m at the beginning of the month and at 21h 27m on July 31, about an hour and a half after sunset, and is not easily observed. Saturn sets about quarter of an hour before the sun on July 1 and is not favourably placed for observation. The earth is at aphelion on July 5.

A total eclipse of the sun takes place on July 9, partly visible as a partial eclipse at Greenwich, where the eclipse begins at 12h 45m and ends at 15h 11m. The magnitude of the eclipse at Greenwich is 0.61. The central line commences in long 115° 57' W and lat 44° 23' N, and ends in long 72° 33' E, and lat 41° 43' N.

Announcements

PROF ARNOLD N SHIMMIN, now acting professor of industrial relations in the University of Leeds, has been appointed to the newly instituted chair of social science in the Department of Economics of the University.

DR KATHLEEN LONSDALE has been appointed by the managers of the Royal Institution to be Dewar Research Fellow in succession to Dr A R Ubbelohde.

THE Committee of Privy Council for the Organisation and Development of Agricultural Research has appointed Prof T G B Osborn, Dr J L Simonsen, and Mr W J Wright as members of the Agricultural Research Council in succession to Prof E J Salisbury, Sir Robert Robertson and Sir Robert Greig, whose terms of office as members of the Council have expired.

THE Library of the Chemical Society is now remaining open for longer hours, it is open from 10 a.m. to 6 p.m. on Mondays to Fridays and 10 a.m. to 5 p.m. on Saturdays.

THE fifth number of the *Revue d'Alger* published by the University of Algiers includes an interpretation of the American constitution, under the title "The Function of the President of the United States", by A Heekscher, an article by G Darmois on "The Tercentenary of the Birth of Newton with an Appreciation of his Work", and one by J Malmejac and S Cruck on "Penicillin: History of a Recent Discovery in Medical Therapy". G Cohen contributes a note on the Free School of High Studies at New York, urging the creation in Paris of a similar school for American students living in France, and M Koch a survey of the French Rhine and its economic and imperial role.

ERRATUM—In his communication on "Calculation of the Results of Microbiological Assays" in *Nature* of May 26, Mr Eric C Woods states that on p 633, line 11, "2 µgm" should read "0.1 µgm".

Night-Sky Emission and Region F Ionization

In the theory of emission of the night-sky spectrum recently proposed by me, the Region F of the ionosphere is identified as the luminescent layer¹. The characteristic night-sky spectrum in the visible region consisting of the first-positive and the Vegard-Kaplan bands of N₂ and the auroral green and red lines of O are supposed to be emitted by the following reaction.

The energy released in the process of neutralization by electron transfer is given by the ionization potential of N₂ (15.58 eV) less the electron affinity of O (2.2 eV). This energy is taken up almost entirely as energy of excitation of N₂ to the B³π state (v' = 9, 9.1 eV) and of O to the ¹S state (4.2 eV). (There is some uncertainty about the value of the electron affinity of O. While Lozier² gives the value as 2.2 eV, recent experiments of Vier and Mayer³ yield the value 3.0 eV. But even with the latter value there is sufficient energy available for raising N₂ to a high vibrational level of B³π, if account is taken of the kinetic energy of the colliding particles.) According to the theory therefore one would expect a positive correlation between variation of the night-sky intensity and variation of the electron content of Region F. Prolonged observations on the intensity of night-sky emission and on the Region F ionization density (square of penetration frequency f_F²) do show unmistakable correlation in respect of long-period variations of the two, for example, seasonal variation and eleven-year solar cycle variation^{4,5,6}.

For the case of short-period nightly variations, however, one would not expect too close a correlation between the two. This is because the nightly variation of f_F² may not correspond to the variation of the total electron content of the region, on which latter, obviously, the intensity of night-sky emission depends. Thus the total number of electrons in a column of unit cross-section may remain constant or even decrease, but f_F² may show an increase due to contraction of the layer as a whole by cooling. Again, the decrease in f_F² due to recombination proceeds much faster than the decrease in the total electron content due to the same cause.

There are, however, 'disturbed' nights on which f_F², as also the intensity of the night sky, vary abnormally. On such nights the variation of f_F² follows the variation of the electron content of the region as a whole and, as such, one may expect a positive correlation between the two. This is precisely what has been found, and furnishes evidence in support of the theory. Taking advantage of the black-out condition in the city, Mr S N Ghosh (Adair Dutt Research Scholar) has, for some time past, been keeping in my laboratory records of night-sky intensity variation on dark clear nights on which f_F² records were also being kept. It was found that on undisturbed nights on which the night-sky intensity shows a typical variation, f_F² also does the same, the two variations not necessarily following each other. On disturbed nights, however, on which f_F² exhibits abnormal varia-

tion, the night-sky intensity also varies abnormally, following the same trend. The accompanying figure depicts two such variation curves. It will be seen that they run approximately parallel to each other.

The night-sky intensity was measured photographically without any filter in the region 6° above the pole star. The photographic records were measured by a Moll microphotometer.

X-Ray Topographs

WHERE a sizable crystal is to be used for investigations of structure-sensitive properties, for example, X-ray intensity measurements, photo-electric effect, etc., it is advisable to test its homogeneity. This may be simply done in the following way.

The crystal is irradiated by a wide beam of appropriately filtered X-rays, diverging from a pinhole placed close to the anticathode. A small piece of flat photographic film is mounted in a holder on the axis about which the crystal oscillates. The film is arranged to be parallel to the face of the crystal which it is required to examine. The crystal is then placed in the position for a Bragg reflexion to occur for this face, and the crystal and film are then oscillated through an angle sufficient for every part of the crystal to reflect. We have found Kodak Process film very satisfactory for this purpose and better than Crystallex, because, though its sensitivity is less, it is much finer grained.

With this arrangement an almost undistorted topograph of the surface of the crystal may be obtained with copper radiation. This is because the characteristic radiation is reflected at a constant angle from all parts of the surface and the image is built up, piece by piece, as the crystal rotates in the diverging beam.

We have investigated a number of diamonds by this method. The topograph of a face sawn through one peculiar interpenetrating twin of diamond is shown in the accompanying photograph, and it is seen that the reflecting power for X-rays varies greatly over the surface. This diamond showed no visible irregularities.

Associated with the stronger reflexions there is frequently found a streak extending sometimes on both sides of the central position. This is due to the 'angular spread' of the polycrystalline material at the reflecting spot. This method is therefore a convenient one for studying variations of texture of the material, which include relatively

large-scale imperfections corresponding to a visible angular spread and small-scale imperfections corresponding to variations in intensity of reflexion at the correct setting of the crystal.

Another diamond which was investigated in this way was sent to us for examination because of its anomalous behaviour in an abrasion test. The stone had been sawn in half, approximately parallel to the cube axis. One half had ground away at the normal rate, the other had proved extraordinarily resistant. Topographs of the ground surfaces were strikingly different, the part which had behaved normally showing a uniform reflecting power, but the part which had behaved abnormally showing obvious irregularities.

Topographs of these two pieces taken on the sawn faces were also interesting, showing quite clearly the existence of a skin. That the outside of a diamond frequently grinds at a different rate from the interior is alleged by most diamond cutters, but the evidence for it that is offered is generally subjective and not easily checked.

While we would not wish to maintain on the basis of this scanty evidence that resistance to abrasion is necessarily correlated with the perfection of the crystal structure, we suggest there is a *prima facie* case for investigation on these lines.

The topographs taken by G. N. Ramachandran¹ are in a sense complementary to those described here. He uses a Laue method and, by making use of hard radiation, examines the whole bulk of the stone, whereas we examine the superficial layers only.

We wish to thank Mr. Paul Grodzinski, of the Research Department of the Diamond Trading Co., for providing the stones and abrasion data, and for permission to publish these results.

Coefficient of Restitution of Coals

In a previous note¹ it was mentioned that mechanical properties are involved in the Stopes classification of the petrological constituents of coals² and they are of interest in any general study of the physical properties of coals. Much of the previous work on this subject has been undertaken from the point of view of mechanical failures in mines, or breakage in handling. Stress-strain relationships for coals have been obtained³ by compression methods using large-scale engineering test machines, and while our experiments were in progress Bangham and Maggs⁴ reported measurements of the elastic modulus of coals in expansion on adsorption of vapours and in mechanical compression on a small scale.

Where the interest lies in the physical structure of coal, it is difficult to get a uniform specimen sufficiently large for direct measurement of the elastic modulus by a simple method. Although the coefficient of restitution is a composite constant, more difficult to treat theoretically, its measurement is simple even with small specimens, and the results are likely to reveal any essential differences in the elastic properties of a series of specimens. The height of rebound of small steel spheres dropped vertically on to a polished plane surface of the specimen was measured for a number of coals of varying rank. The mass of the spheres varied from 0.1 gm. to 12 gm. and the height of fall from 5 cm. to 15 cm. As a check on the technique, blocks of several metals including copper and mild steel were substituted for the coal specimen. It was found that the coefficient of restitution varied with the impact energy of the sphere, but that for any given value of this energy the results were independent of the size of the sphere.

A selection from the results is given in the accompanying graph. Curve 1 is for an anthracite from South Wales, curve 2 for durain from a Warwickshire hard coal, curve 3 for vitrain (with some claram bands) from a Warwickshire bright coal, and curve 4 for copper.

It was found that for all specimens examined, both coals and metals, at very low impact energies the coefficient of restitution tended towards unity with decreasing impact energy. The curves for all specimens of anthracite and durain examined and for metals were similar. With increasing impact energy, the coefficient of restitution drops from the initial high value and rapidly reaches a constant value. The specimens of the lower-rank bright coals, however, all exhibited a minimum in the coefficient of restitution at fairly low impact energies, the coefficient increasing to a constant value at higher energies. This minimum is clearly shown in the graph for Warwickshire bright coal (curve 3). At the higher impact energies the constant values of the coefficient

of restitution for the coals examined varied from 0.75 to 0.90, values considerably higher than those got for metals such as copper (0.62) and mild steel (0.73).

The coals which exhibited a well-defined minimum in the 'restitution-impact energy' curves were all bright coals which are in general much more brittle and friable than durains and anthracites, and in which occur visible cracks and well-defined cleavage planes. The depth of the minimum and the value of the impact energy at which it occurred varied from coal to coal. The minimum could indicate that at each impact an absorption of energy occurs in addition to the elastic strain energy absorbed. The additional amount of energy absorbed would initially increase from zero at zero impact energy, but rapidly reach some constant value independent of the impact energy of the sphere.

While the mechanism of this additional absorption of energy remains obscure, the effect has been suspected by previous workers. Holland² observed that coals subjected to high compression stresses exhibited hysteresis and permanent set, and only 85 per cent of the energy was released on removing the stress, 15 per cent strain energy being absorbed as permanent strain or appearing as heat. He suggested that the violence of rupture observed indicated that a large portion of this energy was released on failure of the specimen. In their mathematical treatment of coal breakage, Bennett, Brown and Crone³ formulated the hypothesis that, under stresses producing breakage, coals behave as brittle materials with a random distribution of inner planes of weakness. On fracture the energy is absorbed in forming new surfaces of the fragmented product, and in the creation of fresh inner weaknesses. As Heywood⁴ pointed out, this hypothesis neglects any elastic strain energy which may be absorbed, that is, assumes perfect elasticity. The experiments described above show that, with impacts too small to produce fracture, elastic deformations occur which absorb energy (since the coefficient of restitution is less than 1) and, in addition, energy is absorbed by some other mechanism in the case of low-rank bright coals. Most of the specimens used were kindly lent by Dr. Bangham of the British Coal Utilisation Research Association.

Explanation of the Broadness and other Characteristics of Association Bands

THE broadness of the OH, NH or similar bands of pure liquids is well known, and there have been many postulates regarding its origin^{1,2,3}. We wish to show here that it is not necessary to assume any involved postulates regarding it, as it can be explained merely from the modern ideas of the mechanism of the formation of the hydrogen bond.

Pauling has shown that a covalent link has a partially ionic character. In the case of OH, for example, H is sometimes an atom enjoying a shared pair of electrons and sometimes a mere proton, the pair of electrons being attracted towards O by its electro-negativity. The two states alternate with what is called a resonance frequency. During the time H is a proton, it can approach another negative atom, say, O, for intense attractive interaction. Thus the H atom in a hydrogen bond moves between two points, say A and B, A being the position nearest to parent O, and where it rests ordinarily in the absence of a hydrogen bond.

Now, corresponding to each point of occupation by H on AB, there will be an OH band, with its own frequencies, and as the force constant will go on decreasing on proceeding from A to B, the breadth of the band is inherent in the formation of a hydrogen bond. Some other pertinent facts associated with hydrogen bonds are also explainable on the above mechanism.

(1) The breadth of the OH band will be greater, the stronger the hydrogen bond. As AB increases with the strength of the hydrogen bond, the breadth increases. Thus carboxylic acids possessing the strongest hydrogen bonds have the widest character of the association bands.

(2) As the concentration of molecules containing OH increases in an inert liquid, the association band will develop as a whole, that is, the character of the band remains independent of the concentration and only the intensity increases. As the association band due to hydrogen bonds arises in a complete form from each pair of molecules involved in a single hydrogen bond, the fact noted above follows.

(3) Since A is the limit of travel of the H proton (this being its rest position in the absence of hydrogen bond formation), the high frequency limit of the association band will end sharply at the high-frequency limit of the normal unassociated OH band.

Hæmolytic Disease of the New-born caused by the Antibody St

RECENTLY hæmolytic disease of the new-born was described¹ where the *Rh*⁺ mother had in her serum an antibody since designated *St*² or γ^3 . From the observations of Race, Taylor and their collaborators^{4,5} the reactions of the known allelomorphs of the *Rh* gene with *St* serum may be summarized thus:

<i>St</i> serum	<i>Rh</i> ₁	<i>Rh</i> ₂	<i>Rh</i> ⁺	<i>rh</i>	<i>Rh</i> ₁	<i>Rh</i> ⁺	<i>Rh</i> ₂
	+	+	+	+	-	-	-

An eighth allelomorph, *Rh*₃, which is *St*⁻, is postulated by R. A. Fisher^{3,6}.

The genotypes found in the St family were mother, Rh_1Rh_1 , first and third children, Rh_1rh , father, Rh_1rh . The first child was unaffected. The second child died from hæmolytic disease, its genotype is not known, but is presumed to have been Rh_1rh . The third child recovered from hæmolytic disease after transfusion with St^- blood. Since this family was first described an unaffected fourth child, genotype Rh_1Rh_1 , has been born, no augmentation of the mother's antibody occurred with this pregnancy.

We have now observed a second family with hæmolytic disease of the new-born caused by the St antibody. The known genotypes are mother, Rh_1Rh_1 , affected child (the second pregnancy), Rh_1rh , father, Rh_2h (Rh_2Rh_2 and Rh_2rh are not distinguishable with the sera available to us, but the father is evidently heterozygous). The first child died in circumstances suggesting hæmolytic disease. The second child, mentioned above, died from hæmolytic disease, and a third pregnancy has recently terminated in abortion at the fourth month.

The mother's serum was examined after her second pregnancy and an antibody was found which agglutinated all of 35 Rh^- group O bloods tested. Identical results were observed using the original St serum and the new serum on a panel of 41 group O bloods (35 +, 6 -). The probability of observing this result by chance is less than 1 in 4 million ($6^1 \times 35^{1/41}$), and it was evident that identical antibodies were present in the two sera. The new serum also gave the 'dosage effect' observed with the original St serum⁴, that is, the titre was considerably higher for erythrocytes containing two St^+ antigens than for those containing one such antigen. It is supposed that in both cases the St^- mother was immunized by foetal rh , the birth of a normal fourth child (Rh_1Rh_1) in the first family is consistent with this hypothesis.

There is evidence^{8,9} that about 90 per cent of mothers bearing children affected by hæmolytic disease are Rh^- , and that the disease results from iso-immunization of the Rh^- mother by an Rh^+ foetus (Rh iso-immunization). The disease is much more likely to appear when the father is homozygous, and every pregnancy (all Rh^+) can provide an antigenic stimulus, in these circumstances the prognosis for future pregnancies in an affected family is entirely unfavourable^{10,11}.

It is of interest to estimate the frequency of matings and pregnancies in which St iso-immunization might occur. If only the common genes Rh_1 , Rh_2 and rh are considered, the mother, who must be St^- , can only be Rh_1Rh_1 . Theoretically, foetal Rh_2 may cause St iso-immunization, and although this does not seem to have been observed it may have occurred with the first and third pregnancies in our second family. From analogy with Rh iso-immunization it would seem that when hæmolytic disease occurs from St iso-immunization and the father is rh or rh , the prognosis for future pregnancies is entirely unfavourable (all children Rh_1rh), and if foetal Rh_2 may cause St iso-immunization the outlook is similarly unfavourable with Rh_2Rh_2 and Rh_2rh fathers. Using the frequencies suggested by Taylor and Race¹² for the common genotypes (rh rh , 13, Rh_1Rh_1 , 19, Rh_1rh , 33, Rh_2Rh_2 , 13, Rh_2rh , 12, Rh_2Rh_2 , 2 per cent) we obtain approximate estimates of matings and pregnancies in which St iso-immunization might occur. (1) Including Rh_2 as an immunizing antigen (a) St^- women and St^+ men, 13.9 per cent of all

matings, (b) St^+ pregnancies with St^- mothers, 1 per cent of all pregnancies. (2) If foetal Rh_2 is included the corresponding figures are (a) 11 per cent (b) 6.7 per cent. Applying the same genotype frequencies to ordinary Rh iso-immunization of rh mothers, we get (a) Rh^- women with Rh^+ men, 10.3 per cent of all matings, (b) Rh^+ pregnancies with Rh^- mothers, 7.3 per cent of all pregnancies. From these data it might be expected that Rh and iso-immunization would occur with about equal frequency, but since some 90 per cent of mothers bearing children with hæmolytic disease are Rh^- , it is clear either that St iso-immunization occurs much less frequently or that its effects are usually unrecognized.

The relative infrequency of recognized St iso-immunization requires explanation, and it may be supposed either that the St^+ antigens are usually weak, or that there is a selective placental impermeability to them. In support of the first hypothesis is the fact that although the occurrence of transfusion reactions from Rh immunization is well established, no similar reactions from St immunization appear to have been recognized.

In addition to the two examples observed by us we are aware of a few other cases of hæmolytic disease in which St antibody has been found, and seems not unlikely that St iso-immunization was responsible for the disease in the three families mentioned by Race, Taylor *et al.*¹⁰ with Rh^+ mothers and Rh^- husbands.

The Race-Wiener Test in Hæmolytic Disease of the New-born

Race¹ and Wiener² described in 1944 independently a peculiar phenomenon concerning the Rh agglutination. When Rh^+ red blood corpuscles were incubated with some sera which did not agglutinate them, after further incubation with potent anti- Rh sera failed to produce an agglutination of these cells. Race called the antibody present in such sera the 'coating' or 'incomplete' antibody, Wiener designated the test as a 'blocking' test and called it the 'counterpart of the inhibition test for haptens and group-specific substances'. Wiener as well as Race and Taylor³ stressed the fact that by means of this test iso-immunization can be detected in Rh^- women when ordinary agglutination tests fail to give such evidence.

No investigations on sera of babies with hæmolytic

disease of the new-born have been yet reported. Anti-*Rh* agglutinins are only exceptionally met with in sera of babies with hæmolytic disease of the new-born. Boorman, Dodd and Mollison⁴ observed, once their presence in twins, and I reported⁵ one weakly positive test in a case of icterus gravis neonatorum. Since then, I have seen one definite reaction in the cord serum of a hydrops foetalis and four weakly positive agglutination tests in icterus gravis neonatorum. Since the publications of Race and Wiener their test has been applied to sera of fifteen babies with hæmolytic disease of the new-born, to nine sera of *Rh*- negative mothers of such babies which gave negative or doubtful reactions in routine anti-*Rh* tests, and to four sera of *Rh*- women with a history of miscarriages but no clinical or serological evidence of iso-immunization. Among the fifteen sera of babies there were seven positive Race-Wiener tests, six negative and two doubtful. All nine sera of mothers of babies with hæmolytic disease of the new-born gave positive results. In the last group there were three negative and one positive result.

Not all *Rh*+ red blood cells are suitable for this test. According to Race¹, sera giving a positive blocking test have an incomplete Δ agglutinin acting on the partial agglutininogen which has been designated by Fisher as *D*. Red blood cells of the phenotypes *Rh*₁, *Rh*₂, *Rh*₃ and *Rh*₄, which together form the majority of *Rh*+ cells, possess the *D*-agglutininogen and can therefore be coated by the incomplete antibody. Fisher's theory appears at the present moment to be the most satisfactory explanation of the intricate *Rh* agglutination phenomena.

I think it premature, however, to be dogmatic about a definite conception of the antigenic structure of the *Rh* factor. We have to realize that Landsteiner's⁶ investigations on conjugated antigens have shown that to a mosaic of serological reactions there need not always correspond a co-ordinate mosaic of chemical structures in the antigen. Whatever be the explanation of the hapten properties in the eight known *Rh* allelomorphs, the fact remains that some *Rh*+ cells fail to be coated in the Race-Wiener test, and that the inhibition may be complete in some specimens and only partial in others. For this reason I always use for the test ten different samples of *Rh*+ red blood corpuscles in two parallel series, one treated with the patient's serum, the other with the serum of an *Rh*+ individual. Into each of ten small test tubes (45 mm length, 7 mm bore, round bottom) 0.04 c.c. of the patient's serum is delivered from a marked Pasteur pipette. In a second series of tubes equal amounts of the control serum are placed. 0.04 c.c. of 2 per cent suspensions of ten different *Rh*+ red blood cells are then run into each tube of the test and control series. Both are incubated for one hour. After this time 0.04 c.c. of a suitable dilution of a potent anti-*Rh* serum is added to each tube, the tubes thoroughly shaken and reincubated for another hour. The test is positive when the majority of samples in the test series show definitely weaker reactions than those in the control series or no agglutination at all. The highest dilution of the standard anti-*Rh* serum which still produced coarse agglutinates in a suspension of standard *Rh*+ cells was considered as suitable for this test.

From the foregoing discussion, it is evident that the Race-Wiener test enables us to diagnose in an appreciable number of cases iso-immunization from the babies' sera, to ascertain iso-immunization when the mother's serum does not agglutinate *Rh*+ cells

and to decide occasionally in cases of *Rh*- women with a history of miscarriages whether iso-immunization has taken place.

Kojic Acid and the Antibiotic Action of Species of *Aspergillus*

It was shown recently¹ that under specified cultural conditions the whole of the antibacterial activity of metabolism solutions from *Aspergillus effusus* Tiraboschi can be attributed to kojic acid. It was suggested that this common mould metabolic product might similarly account for the inhibitory properties of other fungi.

Some time ago, in a preliminary account of the production of antibiotics by selected species of *Aspergillus*², we described the formation by *A. parasiticus* of a material resembling penicillin. In investigating the effect of varying cultural conditions on antibiotic production by this and other species, kojic acid was often observed to be present in the metabolism solutions, but there was ample evidence of the formation of other antibiotics in addition. The observations described below, which were repeatedly confirmed, are recorded with special reference to *A. parasiticus* because of the marked tendency of this mould to produce kojic acid³.

When *A. parasiticus* was grown on a Czapek-Dox synthetic medium with the addition of 0.1 per cent 'Difco' yeast extract, it ceased to give the penicillin-like antibiotic reported earlier, the solutions developed antibacterial activity against *Staphylococcus aureus*, which was not lost on standing the solutions at pH = 1.8 or 11 for 90 min. and was only partly lost after heating to 90° for 30 min. Further tests showed that the antibacterial activity of the culture fluids varied with the amount of sugar present in the medium. In solutions containing 0.5 or 1 per cent glucose, activity against *Staphylococcus aureus* appeared about the twelfth day and the solutions remained active for three to four weeks, colour tests for kojic acid were negative throughout this period and the solutions were entirely inactive against the Gram-negative organisms *E. coli* and *Ps. pyocyaneus*. In 2 per cent glucose solutions kojic acid was present, and slight activity against *E. coli* and *Ps. pyocyaneus* developed from the fifth to the seventh day, after which all activity disappeared until about the thirteenth day, when antibiosis was again produced but against *S. aureus* only, tests for kojic acid were then negative. In 4 per cent glucose solutions the dual phase of activity became still more marked. Activity against *S. aureus* appeared about the fifth day, reached a maximum on the eleventh day and then fell sharply to zero. Tests at 18-22 days were completely negative, but the culture fluids were again

ctive about the twenty-fourth day and were still ctive after fifty days. During the first phase kojic cid was present in the solutions, which were active ot only against the Gram-positive organisms (*Staphylococcus aureus*, *B. megatherium* and *Bact. ziscians*, but also against a range of Gram-negative acteria, namely, *E. coli*, *Ps. pyocyaneus*, *Chr. rodigeosus*, *Ps. fluorescens liquefaciens*, *Bact. aerones* and *B. carotovorus*. During the second phase he solutions inhibited the growth of Gram-positive rganisms only.

When 1, 2 or 4 per cent lactose was used in place f glucose, all the lactose cultures and those containing and 2 per cent of maltose were similar in antibiotic roduction to those containing 1 per cent of glucose, a 4 per cent maltose antibacterial activity exactly aralleled that produced in 4 per cent glucose solutions, with a transient formation of kojic acid during he first phase of activity.

Attempts were made to find convenient substitutes or yeast extract, without which antibiosis was considerably delayed and was less pronounced. Freshly prepared extract of bakers' yeast and an extract of etuue seedlings were effective supplements, but individual compounds such as aneurin, lactoflavin, antiothemic acid, pyridoxine, *p*-aminobenzoic acid, or heteroauxin, were almost valueless. The dual phase of activity when 4 per cent glucose was used n these media was apparent in the culture fluids f all these solutions, though it was not always so learly marked as in the experiments described above.

Clearly at least two antibiotics were produced in hese experiments, the speed of their production apparently depending on the availability of the carbo- ydrate nutrient, but it is possible for the following easons that more than two antibiotics were being ormed. (a) The activities against the range of rganisms examined did not run parallel during the rst phase. For example, in 4 per cent of glucose after eight days, the solutions inhibited *Staph. aureus* t a dilution of 1/100, with only a trace of activity against *E. coli*, after ten days the solution was bout equally effective (limiting dilution 1/100) against these two organisms, whereas after sixteen lays it was less active against *Staph. aureus* than against *E. coli*. (b) During the early part of the first phase of activity, kojic acid was detectable in solu- ion and was readily isolated, its activity proved o be small, as it inhibited *Staph. aureus*, *E. coli* and *Ps. pyocyaneus* at a limiting dilution of 1/2,000–3,000, and there was a very considerable discrepancy between the amounts of kojic acid isolated and he amounts which would have been anticipated if it had been responsible for all the antibacterial activity. Moreover, kojic acid disappeared from the solutions before the latter part of the first phase was reached and did not reappear during the more restricted second phase.

Several products from kojic acid (for example, mono- and di-acetyl, monobenzyl, monomethyl ether derivatives) were examined, but their effectiveness against *Staph. aureus* was negligible. The antibiotic produced during the second phase was easily ex- tracted from acid solution by ethyl acetate and the ctivity could be recovered in neutral solution. The hemical nature of these products is being ex- amined. It is evident in these experiments that ven though kojic acid is produced, only a part f the antibacterial activity can be ascribed to this ompound.

We thank Prof I. M. Heilbron for his encourage- ment and the Rockefeller Foundation for financial assistance.

Root-formation on Cuttings of Plants which Normally do not Root

THE process of rooting of cuttings has proved to be a very complex problem. A good deal of work has shown that root-formation on stem and leaf cuttings depends on many factors, of which auxin and carbohydrate are the most important^{1,2,3}. This work has enabled many investigators not only to produce, more quickly, more numerous roots on cuttings which normally root easily, but also to induce root-formation on cuttings which normally do not root. Thus Cooper^{4,5}, Hitchcock and Zimmerman⁶, and many others have obtained excellent root-formation on cuttings of many economically important plants by application of auxin alone or with sugar solution.

In the present investigation, we are trying to induce rooting of cuttings from *Bougainvillea spectabilis* var. *Lateritia*, and *Mangifera indica*. Cuttings of *B. spectabilis* usually root successfully (success is normally 50–60 per cent), but cuttings from the variety *Lateritia* do not root normally. We have, however, succeeded in inducing root-formation on 50 per cent of woody cuttings from the latter variety by basal application of β -indole acetic acid solution. Different concentrations of the latter have been used for different periods of time, the optimum concentration being 0.015 per cent for a period of twelve hours. Feeding with sugar solution after the application of hetero-auxin did not increase the number of rooted cuttings, thus suggesting that the cause of failure of these cuttings to root under normal conditions is the shortage in the auxin and not the food factor.

Cuttings of *Mangifera indica* have been more difficult to root, but the experiments, which are now in progress, seem to indicate that these cuttings do respond to auxin application. Basal application of β -indole acetic acid solutions induced formation of root initials on these cuttings (collected last autumn), but the cuttings shrivelled and died later in the winter. Cuttings will be collected and treated in different seasons, and the results will be communicated later.

Two Colour-Types in *Solitaria*-Phase Adults and Hoppers of the Desert Locust

COLOUR differences between the *gregaria* and *solitaria* phases in the desert locust, *Schistocerca gregaria* (Forsk.), are well known. In the *gregaria* phase the adults are pink when immature and yellowish when mature (Kunckel d'Hercula¹), *solitaria* adults are greenish when very young and greyish afterwards (Johnston²). *Gregaria*-phase hoppers have a black pattern, *solitaria* hoppers lack this pattern and are green (Johnston², and others) (*Vide* also Kennedy's³ recent account of coloration in *solitaria*.)

I have however observed, both in Nature in Baluchistan as well as in the laboratory, that two distinct colour-types occur in the *solitaria* phase among adults and hoppers. (1) *Adults*. Among 367 adults examined, the majority (about 91 per cent) were suffused with a blue-grey tinge, resembling the *solitaria* individuals mentioned by Johnston, others (about 9 per cent) had no blue-grey but were fawn all over. The occurrence of the two types has no relation to age or season. (ii) *Hoppers*. The majority of *solitaria* hoppers are green. Occasionally, however, both in Nature and in the laboratory, fawn-coloured hoppers, with no trace of green, turn up, as briefly reported earlier in an account of my painted-box experiments (Roonwal⁴). Though exact figures are not available, my distinct impression is that the frequency of occurrence of the fawn hoppers did not exceed about 10 per cent. The colour difference was especially noticeable from the third stage onward, and was not correlated with the environment, as shown by rearing experiments as well as field observations.

It is probable that (a) the fawn hoppers give rise to fawn adults, and green hoppers to the blue-grey adults, and (b) the two colour-types have a genetical significance, since they are not related to phase or environment.

A detailed account will be published elsewhere

Chemical Constitution of the Nucleolar Inclusions in Growing Oocyte Cells

IN many animals during the second period of growth of the oocyte there is a production of nucleolar substance by means of a multiplication of numerous little nucleoli, or the budding of small nucleoli from a principal nucleolus¹. When a principal nucleolus exists, in general concomitantly with the production of the buds, some inclusions with a more or less vacuolar appearance are formed in its interior¹. In a study of the nucleolar physiology in two species of Helicidae—*Helix aspersa* Mull. and *Tachea nemoralis* L.—we have examined the constitution of these inclusions. They are not aqueous vacuoles, though they can be, and probably in general are, less dense than the body of the nucleolus, when centrifuged they are not markedly dislocated and in concentrated salt solutions the volume of the inclusions does not diminish more than the rest of the nucleolus.

By means of the histochemical arginine reaction² we have seen that these inclusions are less rich in arginine than the body of the nucleolus. Millon's reaction for tyrosine and the test for protein SH groups³ are also less strong in the inclusions. On the other hand, Voisenet's reaction for tryptophan⁴ gives a violet coloration more intense in these inclusions.

The Feulgen reaction is completely negative for the nucleolus and the inclusions, while a histochemical test for organically bound phosphorus is positive for the nucleolus body and is more intense in the inclusions. This phosphorus test consists essentially in a slow hydrolysis of the tissues by a molybdate-hydrochloric acid reagent followed by treatment with an acetic solution of benzidine and saturated aqueous sodium acetate⁵. This test demonstrates the presence of phosphorus in thymo- and ribo-nucleic acids, and the reaction is very intense, for example, in the spermatozoa heads and the chromosomes of dividing cells. The test reveals the presence of phosphorus in conjugated phospho-proteins and specially in nucleoproteins.

The coloration of the oocytes with basic (toluidine blue) and acidic (Ponceau PR) stains, minimizing at the same time the adsorption⁶ by addition of 1 per cent saponine, gives results which agree with the histochemical tests. Toluidine blue gives a coloration more intense in the inclusions than in the rest of the nucleolus, while the contrary happens with Ponceau. By means of nucleases extracted from rice bran⁷ we have digested the nucleic acids. After this digestion, the inclusions do not show any differential response to staining and the phosphorus test is negative.

It is known that the nucleolus is formed of, at least, basic proteins and also some non-basic proteins^{7,8}, and nucleotides of the ribose type⁸. It seems that we can safely conclude that the phosphorus reaction, the coloration with basic and acidic stains and the nuclease action, show the existence of nucleotides of the ribose type in the nucleolus, and the nucleolar inclusions must have a greater concentration of these nucleotides than the remaining part of the nucleolus. It would be interesting to test the same material by means of the ultra-violet microscope.

This accumulation of nucleotides in the inclusions is probably related to the production of nucleoproteins rich in basic proteins, by the nucleolus during the elaboration of the cytoplasm and the yolk of the growing oocyte. The nucleoli are more rich in nucleotides (phosphorus test) when young. It is possible that the synthetization of nucleotides is a function of the nucleolar inclusions, while the basic proteins are particularly formed in the nucleolus body.

A Simple Method for the Establishment of Geometrical Progressions by Diluting with the Pipette

In serology and biochemistry it is a daily task to ascertain by so-called serial tests the effective dose of any substance, for example, to establish the titre of the agglutinating power of a serum, to find the strength of a haemolytic amboceptor, or the smallest concentration of salt that just precipitates a colloidal solution, etc

We can carry out the serial tests by preparing solutions of the substance in question in the form of an arithmetical or geometrical progression. Michaelis and Rona¹, and many others, have shown, however, that this procedure as it is often carried out is the source of various errors, when the series are laid out in the form of arithmetical progressions

Let us, for example, examine the sodium chloride series which was prescribed by Kafka for the establishment of the smallest gold-sol precipitating salt concentration (or mastic-sol ones)

Salt conc (%)	0	1	2	3	4	5	6	7	8	9	10	11	12
Difference (%) between various tubes		100	50	33	25	20	16	14	12	11	10	9	

The variation in percentage differences between consecutive concentrations in the above series is clearly undesirable for quantitative estimations. In the great majority of cases it is necessary to estimate, with approximately the same percentage error, at whichever part of the series of dilutions the indicating tubes occur. This is ensured by the use of serial dilutions, in which the ratio of concentrations of the reagent in any two adjacent tubes is the same throughout the series. The preparation of such a geometrical series with any required ratio of concentrations between the contents of adjacent tubes is much facilitated by the use of a simple algebraic formula

A series of tubes is placed in a row. Into the first tube a convenient amount (V) of the reagent is accurately measured. Into each of the remainder of the tubes the same volume of the diluent is measured. Into the second tube is measured also a volume (K) of the reagent, where

$$K = \frac{V}{Q - 1},$$

Q being the ratio of concentration between the contents of adjacent tubes, which is appropriate for the experiment. The contents of tube 2 are then thoroughly mixed and a volume K of the mixture transferred from tube 2 to tube 3. After mixing, a volume K is transferred from tube 3 to tube 4, and so on through the series.

As an example, we may revise the Kafka salt concentration series cited above. If we arrange the twelve dilutions in a geometrical series, the value of Q to cover the range of dilutions from 0.1 to 1.2 per cent is 1.2535. This is arrived at by dividing the difference of the logarithms of 1.2 and 0.1 by 11 (the number of intervals between tubes) and taking the antilogarithms. If we use $Q = 1.25$, the highest concentration should be 1.16 per cent instead of 1.2 per

cent. Then with $V = 0.5$, $Q = 1.25$, $K = \frac{0.5}{0.25} =$

2 c.c., 0.5 c.c. of the 1.16 per cent solution is put into tube 1 and 0.5 c.c. of the diluent into each of the other tubes. The 2 c.c. of 1.16 per cent is added

to tube 2, mixed, and 1 c.c. of the mixture transferred to tube 3, 2 c.c. is then transferred from tube 3 to tube 4, and so on.

If the same pipette is used for each of the successive dilutions, it is important that it should be a very accurate one, as any errors in its calibration cumulate rapidly. If, for example, a 5 per cent deficiency occurs at every stage of successive dilution, the last tube of a series of twelve will have little more than half its true concentration.

In conclusion, I should like to express my sincerest thanks to Dr J. W. Trevan, director of the Wellcome Physiological Research Laboratories, for criticisms and advice.

Potato Dry Rot and Gangrene as Soil-borne Diseases

Dry rot was described as a storage disease of the potato nearly forty years ago^{1,2}, and has since become of increasing economic importance, yet only recently has attention been paid to the soil as a source of infection. The control of the disease obtained by the use of organo-mercury dips at lifting time³ and the marked variation in its severity in stocks of the same variety from different farms lent support to the assumption that the causal fungus (*Fusarium caeruleum*) was soil-borne. No attempt had, however, been made to provide direct experimental evidence of this until last year, when Small^{4,5} showed that *F. caeruleum* was often present in the soil adhering to healthy tubers both at lifting time and during storage.

We have carried out experiments to determine the presence of the fungus in soils from selected fields in Scotland and to discover whether any variations could be detected in the degree of infestation. In the autumn of 1943, bulked random samples of soil were taken, with aseptic precautions, from twenty fields. Potatoes of the susceptible variety Doon Star were inoculated with small quantities of the soils, twenty-five tubers, each inoculated in two places, being used for each sample. A fresh sterilized inoculator was used for each tuber.

RESULTS OF INOCULATING POTATO TUBERS WITH SOIL TAKEN FROM TWENTY SCOTTISH FIELDS IN OCTOBER 1943

Date of last potato crop	Number of fields	Percentage of inoculations causing dry rot
1941	1	32
1942	11	52, 22, 16, 10, 6, 6, 4, 2, 2, 0, 0
1943	8	88, 24, 20, 4, 4, 4, 2, 0
Control sterilized soil		2
Control spore suspension of <i>F. caeruleum</i>		100

The infection of one wound in the first control series was presumably due either to imperfect sterilization or to chance air-borne contamination.

Isolations from random samples of infected tubers showed that the causal organism in almost every case tested was *F. caeruleum*.

The results summarized in the table show that *F. caeruleum* may be present in the soil at least two years after the last potato crop, and that marked variations in the degree of infestation of the soil samples were detected by the method used. Experiments on a larger scale are now in progress to ascertain whether such variations can be correlated with

the amount of dry rot developing naturally in tubers of susceptible varieties taken from the same fields as the soil samples. Further investigation is necessary to determine whether the fungus is a normal inhabitant of certain soils or a soil invader⁶.

Gangrene caused by *Phoma foveata*⁷ has also been assumed to be a soil-borne disease, although, so far, there has been no experimental evidence of this. During a previous experiment we isolated *P. foveata* from typical gangrene lesions developing on some tubers inoculated with soil from two fields in Scotland, both of which had last been cropped with potatoes in 1942, that is, one year before the soil samples were taken. This disease, therefore, may also be regarded as soil-borne.

Details of the above experiments and other work on the epidemiology and control of dry rot are in the course of preparation for publication.

Mass Production of Virus-free Potatoes

UNDER the powers given by the Agricultural Pests Act, 1911, a reserve comprising the Riet River Settlement and all land within ten miles of it¹ has been set aside for growing virus-free potatoes. The Settlement is one of the newer irrigation projects in the Union. It is now being farmed by the State in preparation for the return of men from the armed forces who will occupy it after the War, and it was partly to provide them with a new and profitable industry that the reserve was created.

But primarily the object of the reserve is to break away from the ordinary system of seed production, in which the aphid-transmitted viruses are permitted in small amounts and at least those strains of virus X allowed which cause no visible mottling of the leaves. Circumstances have brought this system about, but although it has been almost universally accepted we should not delude ourselves that it is anything but the makeshift that it is. The plants with aphid-transmitted virus diseases are always a danger, even if they are only few, and except in the very best areas the grower is committed to an endless battle against infection spreading from them. The worst strains of virus X can be kept in check by destroying mottled plants, but under the present system milder strains spread unhindered. A few years ago this might not have seemed a serious objection, but we now know that even the weakest strains which cause no visible symptoms on potatoes substantially reduce the yield^{2,3}.

The only way to deal with virus X in susceptible varieties and the best way with other viruses is to get rid of them altogether. Bald⁴ tells how stocks free from virus X are being grown in Australia. In

Britain the matter has been taken further, and Smith and Markham⁵ describe how the island of Islay off the coast of Scotland is being used for raising virus-free potatoes. Similar isolation is the object of the Riet River scheme, but the scheme goes further and aims not just at producing seed free from every known potato virus, but at supplying it in such quantity that it meets the ordinary demands for good seed. For South Africa, small as its potato industry is, these are put at about five thousand tons a year, or more.

The idea is to have a reserve of sufficient size from which all viruses are excluded. In such a reserve the growers would have a multifold advantage. They would get the highest quality at less cost, partly because they would not be burdened with practices like the removal of infected plants, and partly because yields would reflect the absence of virus X and other infections which depress productivity. In an isolated reserve freedom from virus can be made its own reward, and virus-free seed can be produced not as a speciality, but in bulk and more efficiently than ordinary seed is grown at present. That is the essence of the matter.

The decision to grow virus-free seed at the Riet River Settlement was made several years ago. The area has many advantages. It is well isolated. Disease-carrying aphids are scarce in its hot, dry climate⁶. Experience with the ordinary grade of seed grown there showed that in quality and productivity it equalled anything planted in the Union⁶, Scottish and Irish seed not excepted.

To maintain adequate isolation, regulations made under the Act already mentioned are being used to prohibit the entry of all unauthorized potatoes. For safety's sake, all land within ten miles of the Settlement has been added to the reserve, but few potatoes are likely to be grown there. Outside this boundary (except for an irrigable strip higher up the Riet River which may still be proclaimed) is dry grazing country, too dry for crop farming. Potatoes are planted only in scattered kitchen gardens under irrigation, and then only rarely. The nearest point at which they are grown on any scale worth mentioning is about forty miles away, while there is no intensive potato culture anywhere within a hundred miles. Isolation of this sort will, it is hoped, stop the infiltration of virus into the reserve, but to allow for the chance of occasional introductions the State will continue to grow a small acreage of tested seed which will be used for the frequent renewal of settlers' stocks.

A stock has been built up sufficient to produce the first thousand tons of seed within the next year. So far as one can test, this is free from all potato virus diseases, except leaf-roll, which is present in small amounts. Completely virus-free seed will, it is hoped, be available in bulk a year later.

It is too early to say how far seed production on this type of country can be extended. A full answer must wait until the Settlement's five thousand acres of suitable land are occupied after the War. But there is enough evidence for a preliminary assessment of the position. To the plant pathologist the prospects are favourable. Apart from virus diseases, the climate completely controls *Phytophthora* blight, black leg and powdery scab—to name only tuber-borne infections—and to judge from results in Kansas⁷ gives an easy method of controlling *Rhizoctonia*. Diseases more suited to the climate may still appear, but there is no evidence of them yet. For the agronomist the issues are less favourably

balanced, and it is on him that future expansion really rests. The climate has its virtues. One might mention particularly the remarkable speed of tuber formation which allows main-crop varieties to set a good yield of seed-sized potatoes within six weeks of emergence, and which may probably be attributed to the intense radiation during the fairly short days, and to the great contrast in temperature between day and night. Against these are various cultural difficulties, especially those associated with the high temperature of the soil through which the shoot must emerge. While they have not stopped the rapid building-up of seed stocks in the past, they remain a danger which cannot safely be ignored, and on their solution hangs the possibility of eventually bringing into use the practically limitless area of suitable climate.

⁷ Elmer, O H, *Phytopath*, 32, 972 (1942)

Swimming of *Monas stigmatica*

WHILE not disputing the relatively high speed attained by this organism¹, exception must be taken to Mr A G Lowndes' statement "thus the organism has a relative speed of more than forty, or, in other words, traverses forty times its own length in a second, and on this simple calculation the organism has a relative speed which is twice that of the most modern 'Spitfire' and a thousand times that of a modern destroyer". The figure for a destroyer is nearer two hundred in lieu of one thousand. Moreover, the 'length', for the purpose of such a comparison, should be a dimension in the same plane as the direction of motion.

As this is essentially a hydrodynamic comparison, the well-known law of corresponding speeds should be applied, the correct criterion being speed divided by the square root of the length, and not speed divided by the length as Mr Lowndes states.

The organism as described is a screw propeller rather than a hull. That being so, the most important criterion is the relative speed of rotation. This, by the law of corresponding speeds, is the number of revolutions per unit time, multiplied by the square root of the diameter. If Mr Lowndes can measure the revolutions per second of the organism, it would be extremely interesting to compare its relative rotational speed with that of a 'Spitfire' airscrew or a destroyer propeller.

¹ *Nature*, 155, 579 (1945)

DR TUTIN is a member of the Institution of Naval Architects, and I accept his statement that the relative speed of *Monas stigmatica* is only about two hundred

times that of a modern destroyer. In the past, the relative speed of living organisms has always been expressed as the ratio *distance per sec/length of organism*¹. It would indeed be interesting if one could measure the revolutions per sec of the organism, but I fear this is impossible at present, since it could only be done either by the use of high-speed photomicrography or by the use of the stroboscope attached to the microscope.

A camera giving 1,200 exposures per sec, each exposure of the order of 1/50,000 sec, is normally available here and the cost of film is only about 6d per sec². Unfortunately, owing to the small size of the organisms, high powers of the microscope are essential and this means confining the organisms within a small space and subjecting them to an intense illumination. Under these conditions the swimming of these organisms is quite abnormal, and they usually stop swimming altogether. This being so, neither the film nor the stroboscope would mean anything.

Scientific Material in Occupied Europe

MANY people have been perturbed by reports that the Nazis had applied to scientific material the same process of spoliation and confiscation that they had carried out so systematically in the realm of art. For example, on the liberation of southern Holland, it was reported that the Wasmann collection of ants had been forcibly removed from Maastricht to Berlin.

Recently, however, I have received a letter from Dr Wilhelmina van de Geijn, of the Maastricht Museum, which indicates that in this case the loss has not been so severe as was first feared, thanks to her courage and presence of mind. Readers of *Nature* will be interested to have her account of the incident.

She says (*in lit*, May 6, 1945), "A Berlin entomologic professor, Bisschop, had shown very much interest in our Museum because of the well-known ant collection of Wasmann, which they took or stole and brought it to Berlin. You can read the history in the cutting ('Time' 20 Nov 1944). He threatened me 'Ich werde Sie sofort einsperren', because I refused to tell him where I had hidden the collection, after some discussion with the Nazi mayor they show him the ants. I had some exciting weeks, because I divided the collection and they did not notice it here, but I was afraid that the professor would pay more attention in Berlin—fortunately I never heard anything."

Reports from Belgium and Holland now coming through fortunately suggest that the theft of the Wasmann collection was the act of an individual bully rather than part of a scheme of systematic spoliation.

SOCIETY FOR GENERAL MICROBIOLOGY

THE proceedings of the inaugural meeting of this Society have been reported in *Nature* of March 17, 1945, p 340, together with a brief summary of the address then given by the Society's first president, Sir Alexander Fleming. It is now possible to add some notes on the contents of the interesting papers read at the inaugural meeting.

In the first place, one point in Sir Alexander Fleming's address not previously mentioned will no doubt interest many research workers. Sir Alexander pointed out that team-work is not always an advantage. If, he said, he had been, in 1928, one of a team studying variation in staphylococci, he would, when a mould contaminated one of his culture plates, have "played for the side" and would have gone with the staphylococci, instead of following up the side track which led, by devious paths, to penicillin. "The lone hand has," he said, "advantages as well as the much-advertised team-work, but each in its own place."

There are many who will agree with this. Team-work can be over-emphasized, and better results, outside the field of 'applied' research at any rate, may come from the looser associations between individuals working in the closely inter-related laboratories of different branches of science in residential universities. These are teams with a difference, and perhaps the difference is often vital to discovery. It could, indeed, be argued that, if we had more residential universities of moderate size, fewer scientific societies would be required and more discovery would result. If teams were needed for organized attacks upon selected problems, these could then be the more easily recruited from groups of men who would work better together because they always had been working together and knew each other's strengths and limitations.

The importance of the constant intercourse of individuals provided by a residential university cannot be over-estimated. It was, in fact, brought out by Dr Marjory Stephenson in her paper on "Levels of Microbiological Investigation." As knowledge increases, she said, and technique becomes more difficult, interdepartmental collaboration is "strongly indicated." Workers must be refreshed by contacts with work at other levels, and she gave a table illustrating the levels to which she referred. None of these, she insisted, is to be regarded as higher or lower than any of the others. At level *A*, represented by the early Pasteur period from 1858 onwards, and by modern work on marine, river and lake populations, on ruminant digestion and the soil, mixed cultures of organisms growing in natural environments are used. At level *B*, represented by the later Pasteur period from 1876 onwards, pure growing cultures of organisms in laboratory media are used. To this level belong the great triumphs of medical bacteriology, which resulted in the isolation in pure culture and identification of causal agents of infectious diseases, specific fermentation and chemical changes in the soil. Most medical and epidemiological bacteriology is still done at this level and almost every modern discovery must begin here, but this technique cannot reveal the mechanism by which the effects of a given organism revealed by it are brought about. At level *C*, dating from 1919 onwards, the substrate is simplified and a beginning is made with the study of the mechanisms by which an organism in pure culture produces its chemical effects. Non-proliferating cells in

pure culture on chemically defined substrates are used. This method gave us the early studies on intermediary processes of fermentation, on the use of poisons, inhibitors and fixatives, and also the early studies on oxidation, reduction, deamination and so on. At level *D*, dating from 1930 onwards, pure growing cultures in highly purified media are used, this level has given us detailed studies of growth requirements, nutritional needs, chemotherapy and microbiological assay. At level *E*, beginning in 1940, cell-free enzymes and co-enzymes in pure substrates are employed. It is a development of level *C*, but the enzymes are separated and it is shown how each produces its effect on its own particular substrate. Greater precision is provided in our knowledge of fermentation processes and correlation with the chemical activity of animal and plant tissues. It is not confined to filterable enzymes. Enzymes can now be extracted from the bacterial cell itself (for example, from *Bact. coli*), and study and work of this latter kind is nowadays gathering momentum and volume.

These levels represent different methods of technical approach. The workers at each level are dependent upon each other, because facts established at levels *A* and *B* provide the starting-point for work at levels *C*, *D* and *E*, and results obtained at levels dealing with enzymes must be referred back to level *B* for epidemiological verification and animal experiment. Incidentally, Dr Stephenson put in a plea, which many will support, for the abolition of the terms 'fundamental' and 'pure' science.

Mr F C Bawden, discussing plant viruses, reminded the Society that viruses were discovered by the breakdown of bacteriological techniques, namely, by the discovery that an apparently sterile filtrate was infectious. The chief techniques of the bacteriologist are therefore not suited to the study of viruses. The protein chemist provides the most useful new techniques. Several viruses have been obtained from nucleoproteins and some are fundamentally different from organisms, chemically they are less complex and their internal structure is much less regular than that of the simplest known organisms. In their purified state they resemble constituent parts of organisms rather than whole organisms, and we may ultimately have to deal with them as such. They are favourable material for the study of mutations and multiplication, and they are attractive subjects for the protein chemist. Plant viruses provide excellent antigens for serological studies, they readily produce antibodies when they are put into animals. The study of viruses brings together workers in widely separated fields.

Prof W B Brierley used the grey mould, *Botrytis cinerea*, to illustrate his discussion of problems presented by the micro-fungi. The morphology of these organisms is no guide to their physiology, for two individuals may look alike and bear the same name (for example, *B. cinerea*) and yet show very wide difference in behaviour. The unit of behaviour is the experimentalists' strain of the organism. Discussing the value of morphological, cultural and physiological criteria for the delimitation and characterization of species, varieties and strains, and the genetic and taxonomic relationships of these categories in the light of variation in the microfungi, Prof Brierley concluded that we urgently need genetic and behavioural study which aims at systematic grouping on a cultural and behavioural basis at the level of the strain.

The importance of the general theme discussed by

reley is underlined by the trend of discovery than one field of biological research. In biology, for example, the existence of what are 'physiological strains' of certain species of which are morphologically indistinguishable have long been known. Epidemiologically these are often very important. Thus it is not to distinguish structurally *Ascaris lumbricoides* the pig from *A. lumbricoides* of man, yet, when infected himself with *A. lumbricoides* from the pig, he suffered only respiratory symptoms due to migration of the larvae to his lungs, and the pig was unable to develop to the adult stage in his lungs. It has been claimed, conversely, that the strain of *A. lumbricoides* will not develop to the adult stage in the pig, although it may do so in the human. That the experimental pig's resistance is due to a diet deficient in vitamin A. Similar physiological strains of the sheep stomach worm, *Haemonchus contortus*, and the gapeworm *Syngamus trachea* in poultry have also been recognized. The subject was further discussed in the paper given at the meeting of the Microbiological Society by Dr. Cecil A. Hoare, who described the morphologically identical but physiologically different strains of certain Protozoa. In many of these strains exist among the blood-sucking Protozoa, their host-relationships are different from several points of view. Some strains differ from each other in their host specificity, others in the different diseases in the same host, others in their degree of virulence to the host. These physiological groups include both races which are stable and hereditarily fixed and strains which are environmentally induced and unstable, the latter being comparable to the so-called 'enduring modifications' (*dauermodifikationen*). Biological races of Protozoa are equivalent to the 'types' recognized among the bacteria. The available data indicate that in both groups the differences between the groups in question are determined by the same factors, namely, variation in antigenic composition. In both Protozoa and Bacteria, therefore, the distinction between biological races resolves itself into differences in the chemical constitution of their antigens. Dr. Frey directed attention to the unsatisfactory nature of the nomenclature used for biological groups in general, and suggested that biological races should be assigned to an independent systematic position, representing a taxonomic unit subordinate in rank to species or subspecies. With this most parasitologists, in any rate, will agree. Some such measure is indeed being forced upon them by the epidemiological and the consequences of modern work on the host-parasite relationships of many kinds of parasites. No doubt the necessity for it will be even clearer and the scientific basis for it will be provided when improvements in the technique of the cultivation of metazoan parasites makes possible work at the levels *D* and *E* suggested by Dr. Stephenson.

Dr. R. H. Hopkins, discussing yeasts, pointed out that the chemist's conception of yeasts as unicellular budding organisms which produce alcoholic fermentation of certain sugars does not coincide with the 'true yeasts' or the 'yeast-like fungi' of the biologists. Earlier classifications of the yeasts are to be replaced by a classification based upon physiological work. The introduction of a synthetic medium to remove discrepancies due to the variable composition of media upon which yeasts are grown. In recent genetic work, Prof. Hopkins suggested that from it we may expect not only a new

and sound system of classification, but also perhaps improved yeasts, for industrial purposes, produced by planned breeding. While the breeding of hybrids is confined to spore-forming yeasts, new yeast types may result from mutations induced by irradiation, toxic chemical agents, such as lithium chloride, cyanides and camphor, and other means, and these methods should be applicable to non-spore-forming yeasts also. Among examples of this kind of work given by Prof. Hopkins was Thaysen's production of *Torulopsis utilis* var. *major* by the use of camphor (*Nature*, 152, 526, 1943).

Dr. A. T. R. Mattick discussed some basic problems of dairy bacteriology. One of these is the resistance of bacteria to heat, which is intimately connected with the sterilization of milk equipment and with pasteurization. Cheese-making provides the problem of the lactic streptococci which are normally added to milk to produce the lactic acid necessary for the optimum coagulation due to rennet, but these streptococci produce, if they are heated above the normal cultivation temperature of 22° C, large quantities of acetic acid, and at lower temperatures other products appear. The practical importance of bacteriophage in cheese-making is considerable, for bacteriophage freely attacks the lactic streptococci used, and strains of streptococci insusceptible to local bacteriophages are needed. Dr. Mattick also described the steps by which he and Mr. A. Hirsch (see also *Nature*, 154, 551, 1944) developed the work of Whitehead in New Zealand on the substance or substances recoverable from milk which inhibit the growth of streptococci used to start the production of acid. Mattick and Hirsch found that this inhibitory substance inhibits also, both *in vitro* and *in vivo*, the growth of some streptococci which are pathogenic to man and also that of certain acid-fast bacteria, including *Mycobacterium tuberculosis*. It is possible that this substance may be useful for the control of bovine mastitis. The work being done at the London School of Tropical Medicine upon what is apparently the same substance has already been noted in *Nature* (155, 584, 1945). In cheese-making, said Dr. Mattick, the moulds are also important, for they are used to ripen some of our choicest cheeses. Thus *Penicillium roqueforti* ripens Stilton cheese, but the strain used makes "a world of difference to the flavour".

Dr. G. H. Wooldridge, discussing the relationship of veterinary science and microbiology, said that veterinary science has gained much from the work of microbiology and has also contributed its share to our knowledge of microbiology. He gave many examples of outstanding work by veterinarians. To them we owe much of our knowledge of anthrax, tuberculosis, glanders, rabies, foot and mouth disease, braxy, rinderpest, the diseases of sheep caused by anaerobic bacteria and other diseases which may profoundly affect human civilization. The discovery made by Griffith Evans in 1850 that surra is due to a trypanosome was the forerunner of the work of Bruce, a medical man, on nagana, a disease of horses due to a trypanosome, and Bruce applied that work to the study of human trypanosomiasis. Co-operation between the medical man Theobald-Smith and the veterinarian Kilburn in the United States discovered that red water fever in cattle is due to a piroplasm transmitted by a tick. Veterinary workers should study more intensively the host-parasite relationship and the control of the spread of disease.

U.S. NATIONAL PATENT PLANNING COMMISSION: SECOND REPORT

IN its first report on the American patent system, the National Patent Planning Commission directed attention to certain aspects of the general operation of the patent laws. The present report* deals with the administration of patents that have come to be owned outright by the Government and also with the respective rights of the Government and its employees and contractors in inventions evolved during the employment or contractual relationship.

On the matter of government-owned patents, the Commission recommends that the Government should "as a general rule continue to pursue the historic policy of not exercising the right to exclude conferred by patents which it owns, of not attempting to exclude its own citizens from engaging in any enterprise, of not seeking to derive revenue from patents, and of not undertaking control by means of patents. Inventions covered by patents owned by the Government should be available for commercial and industrial exploitation by anyone, with, however, the recourse open to the Government to take different action in exceptional cases." In recommending the Government to continue to follow this historic policy and to make inventions covered by Government-owned patents available for exploitation by anyone, the Commission recognizes that there are many patents on inventions developed by, or for, the Government that would be of great public benefit if they were commercially exploited. What prevents such inventions from being commercially exploited, however, is that manufacturers are generally unwilling to make substantial investments in commercializing them if they are also available to competitors. The Commission therefore recommends that suitable legislation should be enacted to confer on the Government the power to grant exclusive licences or to assign Government-owned patents "under appropriate conditions and safeguards whenever it is determined that such action is necessary to assure the commercial development of an invention of a Government-owned patent."

On the policy to be followed regarding the respective rights in employee inventions, the Commission finds that Government policy has not been uniform, but, even so, recommends that it should not be governed by rigid rules prescribed in advance for all departments and all cases. The opinion is expressed that it should be a matter primarily for departmental treatment and in the two extreme cases, first, when an employee is employed to invent and, secondly, when an employee makes an unrelated invention by use of his own time and facilities, the rule of the general law should be followed. In departments confronted with substantial patent problems, general regulations should be maintained or promulgated.

In the report it is stated that a considerable amount of governmentally subsidized research in connexion with the War is being conducted by educational institutions and by private concerns under Government contracts, and that patent rights resulting from such research have been disposed of in various ways. A common feature of these ways is a contractual

clause by which the Government has the obtaining licences on reasonable terms, Commission expresses the opinion that patent clause is unfeasible and undesirable each case should be decided in accordance with facts involved.

In order to correlate the patent policies of the various Government agencies, the Commission recommends that there should be a central control body, in the Executive 'President, having the following principal functions and duties:

(a) Promulgating general policies and approving departmental policies regarding employee inventions, and determining disputes.

(b) Supervising and approving the management of patent rights by the individual departments, including granting exclusive licences for Government-owned patents.

(c) Instructing and advising departmental agencies, collecting information, conducting investigations, and making appropriate recommendations.

In commenting in *Nature* (153, 12, 194) on the First Report of the National Patent Planning Commission, it was pointed out that the numerous technical changes recommended by the Commission were almost uniformly such as to bring the American patent system more closely in line with that of Great Britain, the same principles being applicable to the present report. The British system, acting through the Department of Science and Industrial Research and the Imperial College of Science, Technology and Industry, has power, which the Commission recommends be conferred on the Government of the United Kingdom, to assign or to license patents owned by it. The procedure suggested by the Commission for dealing with employee inventions is in close agreement with the procedure established many years ago in Britain as a result of the report of the Departmental Committee on Patents presented by Sir Kenneth Lee.

WILLIAM S. JARR

THE MENISCUS TELESCOPE

IN the Soviet Union at the present time, a new system of telescope construction is engaging the interest of astronomers and those concerned with the erection of telescopes, whether for research or for instructional purposes in schools. The system, called the meniscus catadioptric system, worked out in 1941 by Dr D. D. Maksutov of the State Optical Institute. The principles involve the advantages to be derived therefrom have been described by Dr Maksutov in an article which appeared recently in the journal *Nauka*, published by the Academy of Sciences of the U.S.S.R.

In its simplest form, the optical system of the meniscus telescope comprises a single thick mirror with spherical surfaces concave to one another, in which is placed some distance in front a silvered or aluminized, spherical mirror. This produces a diverging lens of exceedingly low power, which produces appreciable spherical aberration, but, for example, from a star, focal rays, for example, from a star, focal rays, remain nearly parallel after reflection and are reflected back by the mirror, forming an image between the mirror and the meniscus. Spherical aberration is produced.

* Government-owned Patents and Inventions of Government Employees and Contractors. Second Report of the National Patent Planning Commission. Pp 27 (Washington, D.C., 1944).

Prof. is and the mirror, but one is positive and the other is negative. It is this fact which is the basis of the theory and the design of the meniscus telescope. They have been built. Maksutov has succeeded in that by suitable selection of the radii of curvature of the meniscus and mirror, the thickness of the meniscus and the quality of the glass used, it is possible to arrange that the spherical aberration of the mirror is compensated for by the spherical aberration of the meniscus lens. In addition, the meniscus permits the almost complete removal of coma. By these means, sharpness of image in the field of view is readily attainable. Maksutov has also shown that it is only necessary to take into the calculation the distance between the meniscus and the mirror to establish the conditions for a field of view which will be well defined by an area sufficiently great for all practical purposes.

The principle may be used in various types of complex telescopes. The accompanying figure shows one such type. Here the meniscus and mirror are placed closer together than is usual in the Simeiz type, and the centre portion of the meniscus is so placed that the reflected rays from the concave mirror fall on the meniscus, are reflected by the convex mirror, pass through an opening in the meniscus and form the image.

The meniscus telescope combines most of the good features of both refractors and reflectors and eliminates the unsatisfactory features. It is extremely compact and powerful; it is generally of closed construction, like a refractor, and it is achromatic, like a refractor. Moreover, it is of great significance, from the point of view of simplicity and cheapness of manufacture, that all the optical elements are parts of spherical surfaces.

The superiority of the meniscus type over the other two main types of telescopes used for astronomical purposes may be illustrated by taking as examples, the Yerkes refractor, the Simeiz reflector and the meniscus telescopes now planned for construction in the USSR. These examples are comparable since the aperture in each case is 1 m. The Yerkes refractor has a tube-length of 20 m., and the object-glass consists of two pieces of optical glass (crown and flint), but in spite of its great length, the quality of the image obtained is poor on account of chromatic aberration. The Simeiz reflector (now destroyed) had a parabolic mirror 1 m. diameter and its tube-length was 17 m. The image quality at the centre of the field was faultless, but it deteriorated rapidly towards the edges. The meniscus telescope referred to has a tube-length of a little less than 3 m. It is expected to be sharp over a fairly wide field. Its power will be considerably greater than that of a reflector of similar diameter. It will consist of one lens in optical glass. Crown glass or, indeed, almost any type of glass, could

be used, but crown glass has naturally been chosen since it is more transparent to violet and ultra-violet light.

Because of the reduction in size the cost of building observatory domes, etc., will be much less with meniscus telescopes than with other types. It is estimated that the Simeiz type and the Yerkes type would cost four times and seventy times, respectively, the amount which will be expended on a 1 m. diameter meniscus telescope.

Many observatories, together with their equipment and instruments, have been destroyed during the War, but Soviet astronomers are determined on the speedy restoration of these and the construction of new observatories where instruments, embodying all the refinements of recent research, will rival the best available elsewhere. They are planning, also, an increase in the number and size of university observatories, and they are proposing to establish smaller telescopes in both town and country schools. The meniscus type of telescope offers the best means of achieving these aims with the minimum of delay and the minimum of expense.

G. STANLEY SMITH

¹ Maksutov, D. D., *Nauka i Zhizn (Science and Life)*, No. 9, p. 1 (1944). The theory is described in detail and dimensional particulars are given under the reference Maksutov, D. D., *J. Opt. Soc. Amer.*, 34, 270 (1944).

RECENT WORK ON RHENIUM

IN the two decades since rhenium (Mendeléeff's dwi-manganese) was discovered, hundreds of its compounds have been reported. Among the latest are some stable complexes in which the element is present as the cation. Lebedinsky and Ivanov-Emm (*J. Gen. Chem., U.S.S.R.*, 13, 253, 1943) have described the complexes derived from saturated solutions of the double chlorides, K_2ReCl_6 and K_2ReCl_5 , by using a large excess of ethylene diamine. This is apparently the only suitable base, since ammonia and pyridine do not react in the same way. During the reaction, rhenium oxidizes to the pentavalent state and $ReO_2(C_2H_4N_2H_4)_2Cl$ separates. It gives no precipitates in aqueous solution except with cobaltinitrites and platinum chlorides.

A corresponding iodide, only slightly soluble in water, was obtained by metathesis with potassium iodide. When treated with hydrochloric acid the substances yield $ReO(OH)(C_2H_4N_2H_4)_2Cl_2$, which is isolated from its saturated solutions by precipitation with alcohol. A curious compound, $ReO(OH)(C_2H_4N_2H_4)_2PtCl_6$, results when the chloride is mixed with sodium platinum chloride solution. A corresponding iodide is also known. Both are only slightly soluble in water, but the solutions contain rhenium ions.

When rhenium salts were first obtained there was some controversy over the efficacy of hydrogen sulphide as a reagent for precipitating rhenium as sulphide. Geilmann and Lange (*Z. anal. Chem.*, 126, 321, 1944) now state that the heptasulphide is completely precipitated from slightly acid solutions by hydrogen sulphide under pressure, especially if the mixture is heated for half an hour before filtering. For estimating rhenium the washed precipitate is converted into sodium per-rhenate with sodium hydroxide and perhydrol and then re-precipitated as nitron per-rhenate. Rhenium compounds fused with sodium carbonate and sulphur yield an insoluble alkali complex.

Another selective reagent, toluene-3,4-dithiol, is found to give a green complex with rhenium (and also with molybdenum) and a blue one with tungsten (Miller, *Analyst*, 69, 112, 1944). The *K*-absorption limit for rhenium is reported to be 172.66 by Manescu (*C.R. Acad. Sci.*, 216, 732, 1943) who examined its salts between 'Cellophane' sheets using a potential of 100–125 kV.

According to Naray-Szabo, rhenium trioxide crystals are cubic (*Naturw.*, 31, 466, 1943).

FORTHCOMING EVENTS

Saturday, June 30

ASSOCIATION FOR SCIENTIFIC PHOTOGRAPHY (at the Alliance Hall, Westminster, London, S.W.1), at 2.30 p.m.—Mr H. White "Make the Photograph tell a Story."

Friday, July 6

PHYSICAL SOCIETY (at the Royal Institution, Albemarle Street, London, W.1), at 5 p.m.—Prof. Arturo Duperier "The Geophysical Aspect of Cosmic Rays" (29th Guthrie Lecture) (Fellows of the Royal Astronomical Society and members of the Royal Meteorological Society are also invited to attend).

Saturday, July 7

SOUTH-EASTERN UNION OF SCIENTIFIC SOCIETIES (at the Rothamsted Experimental Station, Harpenden), at 9.30 a.m.—Fiftieth Annual Congress Prof. W. G. Ogg "Some Aspects of the Work at Rothamsted."

INSTITUTE OF PHYSICS (LONDON AND HOME COUNTIES' BRANCH) (in the Physics Department, Imperial College of Science and Technology, South Kensington, London, S.W.7), at 2 p.m.—Discussion on "The Corrosion of Metals."

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned.

CIVIL ENGINEER by the British Overseas Airways Corporation, for control and supervision of civil engineering and building work in the India and Burma Region—The Ministry of Labour and National Service, Central (T and S) Register, Room 5/17, Sardina Street, Kingsway, London, W.C.2, quoting E 1659 XA (July 6).

LECTURER (full-time) IN ELECTRICAL ENGINEERING—The Principal, Handsworth Technical College, Golds Hill Road, Birmingham, 21 (July 7).

LECTURER-IN-CHARGE OF THE CHEMISTRY DEPARTMENT EVENING CLASSES in the East Ham Technical College, to be responsible for organization and development of part-time courses up to Higher National Certificate standard and courses in both Pure and Applied Chemistry—The Chief Education Officer, Education Office, Town Hall Annex, Barking Road, East Ham, London, E.6 (July 7).

ASSISTANT LECTURERS IN BOTANY, GEOGRAPHY (climatology and cartography), and ZOOLOGY—The Registrar, University College, Exeter (July 9).

BOROUGH ELECTRICAL ENGINEER AND MANAGER—The Town Clerk, Town Hall, Leigh, Lancashire (endorsed 'Borough Electrical Engineer and Manager') (July 10).

WATER ENGINEER AND MANAGER—The Town Clerk, Council Offices, North Street, Chichester, Sussex (endorsed 'Appointment of Water Engineer') (July 11).

DIRECTOR OF WORKS by a Governmental Office (candidates must be Corporate Members of the Institution of Civil Engineers and must have had experience in carrying out constructional work abroad)—The Ministry of Labour and National Service, Appointments Department, A.9, Room 5/17, Sardina Street, Kingsway, London, W.C.2, quoting E 1700 A (July 13).

ASSISTANT ADVISER IN PLANT PATHOLOGY—Prof. R. G. White, School of Agriculture, University College of North Wales, Bangor (July 14).

DEMONSTRATOR IN THE PHYSICS DEPARTMENT, for general teaching duties—The Dean, Guy's Hospital Medical School, London Bridge, London, S.E.1 (July 14).

LECTURER IN PHYSICS—The Principal, Royal Holloway College, Englefield Green, Surrey (July 14).

GARDENING INSTRUCTRESS for a County Technical School for Girls with a demonstration garden at Chislehurst—The County Education Officer, Springfield, Maidstone (July 14).

ASSISTANT LECTURER IN CHEMISTRY, and an ASSISTANT LECTURER IN CLOTH MANUFACTURE, at the Bradford Technical College—The Director of Education, Town Hall, Bradford (July 14).

ASSISTANT LIBRARIAN in the University Library, and a SUB-LIBRARIAN in the Faculty of Engineering—The Registrar, The University, Liverpool (July 15).

PROFESSOR OF CHEMICAL TECHNOLOGY at the University of Madras—The Registrar, University of Madras, Chepanik, Triplicane, Madras (by Air, July 15, copy to the High Commissioner for India, General Department, India House, Aldwych, London, W.C.2).

LIBRARIAN—The Secretary, The University, 38 North Bailey Durham (July 16).

ASSISTANT LECTURER IN HORTICULTURE with special qualifications in Horticultural Machinery—The Registrar, The University, Reading (July 16).

RESEARCH OFFICER FOR SPECTROSCOPIC INVESTIGATIONS, Division of Industrial Chemistry, Council for Scientific and Industrial Research Melbourne—The Secretary, Australian Scientific Research Liaison Office, Australia House, Strand, London, W.C.2 (July 16).

LECTURER IN GEOGRAPHY (with special qualifications in Cartography)—The Registrar, The University, Reading (July 16).

LECTURER (or ASSISTANT LECTURER, according to qualifications) IN THE DEPARTMENT OF BOTANY—The Secretary, King's College Strand, London, W.C.2 (July 20).

SECOND ASSISTANT PETROLEUM TECHNOLOGIST in Trinidad—The Ministry of Labour and National Service, Appointments Department, A.9, Room 5/17, Sardina Street, Kingsway, London, W.C.2, quoting F 4411 A (July 21).

SCIENTIFIC ASSISTANT—The Deputy Director, Imperial Bureau of Dairy Science, Shinfield, Reading, Berks (July 21).

UNIVERSITY LECTURER IN GEOLOGY—The Secretary of the Appointments Committee of the Faculty of Geography and Geology, Department of Mineralogy and Petrology, Cambridge (July 30).

SECRETARY TO THE UNIVERSITY COUNCIL—The Secretary, University Registry, Cathays Park, Cardiff (July 31).

LECTURES IN CHEMISTRY—The Registrar, Trinity College, Dublin (August 20).

WARDEN OF CREWE HALL (the University Hall of residence for Men) who must be a graduate and will be required to give some part in University teaching—The Registrar, The University, Sheffield (August 31).

CHAIR OF MEDICINE in the University—The Registrar, The University, Sheffield (October 31).

CHAIR OF SURGERY tenable at the British Postgraduate School—The Academic Registrar, University of London College, Richmond, Surrey (January 1).

LECTURER IN CHEMISTRY, with qualifications in Organic Chemistry—The Registrar, University College, Exeter.

LABORATORY ASSISTANT (man or woman) FOR THE BIOMEDICAL RESEARCH LABORATORY—The Warden and Secretary, London (Royal School of Medicine for Women, 8 Hunter Street, London, W.C.1).

LABORATORY APPRENTICES (boys or girls) IN THE DEPARTMENT OF BOTANY, PHYSICS, PHYSIOLOGY AND ZOOLOGY—Bedford College for Women, Regent's Park, London, N.W.1.

RESEARCH MANAGER, a CHIEF CHEMIST, CHEMISTS (2 or 3) with some years research experience, and CHEMISTS and PHYSICISTS—The Director, Paint Research Institute, Teddington, Middlesex.

TEACHER IN ENGINEERING SUBJECTS up to Higher National Certificate standard in day, part-time, and evening classes—Erith Technical College, Belvedere, Kent.

TEACHER (well qualified) OF SCIENCE—The Principal, Institute, Tunbridge Wells.

LECTURER (full-time) IN THE PHYSICS DEPARTMENT—The Principal, Northampton Polytechnic, St John Street, London, E.C.4.

HEAD OF THE ENGINEERING DEPARTMENT—The Registrar, College, Portsmouth.
